Lecture 16 Functions

Heng Huang, Ph.D.
Department of Computer Science and Engineering

## Functions

- Some common functions

$$
\begin{aligned}
& y=x^{2} \\
& y=x^{1 / 2}-\sin x .
\end{aligned}
$$

- Definition

Let $S$ and $T$ denote two sets. A function (mapping) from $S$ to $T$ (denoted by $f: S \rightarrow T$ ) is a subset of $S X T$, in which each member of $S$ appears exactly once as the first component of an ordered pair. S is called the domain and T is called the codomain of the function. If $(\mathrm{s}, \mathrm{t}) \in \mathrm{f}$, then we write $\mathrm{t}=$ $f(s) ; t$ is the image of $s$ under $f$ and $s$ is the pre-image of $t$ under $f$. For $A \subseteq S, f(A)=\{f(a): a \in A\}$.

## Examples

- Is $\mathrm{f}: \mathrm{N} \rightarrow \mathrm{N}$ a function, where $\mathrm{f}(\mathrm{x})=\mathrm{x}^{1 / 2}$.
- Is $\mathrm{f}: \mathrm{N} \rightarrow \mathrm{R}$ a function, where $\mathrm{f}(\mathrm{x})=\mathrm{x}^{1 / 2}$.
- Is $g: N \rightarrow N$ function, where

$$
\begin{aligned}
\mathrm{g}(\mathrm{x}) & =\mathrm{x}, \text { if } \mathrm{x}<=5 \\
& =10-\mathrm{x}, \text { if } 5<=\mathrm{x}<=10 \\
& =\mathrm{x}, \text { if } \mathrm{x}>=11
\end{aligned}
$$

- Functions can be defined on more than one variable; for instance, $f: N X N \rightarrow N, z=x^{2}+y^{2}$.

## Function Fundamentals

- Definition

Two functions $f$ and $g$ are said to be equal, if they have the same domain, the same co-domain and the same association of values in the co-domain with values in the domain.

- Example

Let $S=\{1,2,3\}$ and let $T=\{1,4,9\}$. Let $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ be defined as follows: $\mathrm{f}=\{(1,1),(2,4),(3,9)\}$. The function g : $\mathrm{S} \rightarrow \mathrm{T}$ is defined as follows:

$$
g(n)=\frac{\sum_{k=1}^{n}(4 k-2)}{2}
$$

Is $f=g$ ?

## Onto Functions

- Let $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ denote an arbitrary function. Let $\mathrm{R}=\{\mathrm{t} \mid \mathrm{t} \in \mathrm{T}$ and $t=f(s)$, for some $s \in S\}$, i.e., $R=f(S)$. $R$ is called the range of $f$; clearly $R \subseteq T$. If $R=T$, then $f$ is called an onto (or surjective) function.
- Example
- Is $f: R^{+} \rightarrow R$ defined as $f(x)=x^{1 / 2}$ surjective?
- Is $f: R^{+} \rightarrow R^{+}$defined as $f(x)=x^{1 / 2}$ surjective?
- Is $f: R \rightarrow R$ defined as $f(x)=x^{2}$ surjective?
- Is $f: R \rightarrow R$ defined as $f(x)=x^{3}$ surjective?
- In order to show that a function $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ is surjective,
- Pick an arbitrary element $t \in T$.
- Show that there exists some $s \in S$, such that $f(s)=t$.

## One-one Functions

- A function $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ is said to be one-one or injective, if distinct elements in S have distinct images in T .
- Example
- Is $f: R \rightarrow R$ defined as $f(x)=x^{2}$ injective?
- Is $f: R \rightarrow R$ defined as $f(x)=x^{3}$ injective?
- In order to show that a function $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ is injective,
- Show that for arbitrarily chosen $a, b \in S$, $a!=b \rightarrow f(a)!=$ $\mathrm{f}(\mathrm{b})$.
- Alternatively, show that for arbitrarily chosen $f(a), f(b) \in$ $\mathrm{T}, \mathrm{f}(\mathrm{a})=\mathrm{f}(\mathrm{b}) \rightarrow \mathrm{a}=\mathrm{b}$.

## Bijections

- Definition

A function $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ is said to be bjiective if it is both injective and surjective.

- Example
- Is $\mathrm{f}: \mathrm{R} \rightarrow \mathrm{R}$ defined as $\mathrm{f}(\mathrm{x})=\mathrm{x}^{2}$ bijective?
- Is $\mathrm{f}: \mathrm{R} \rightarrow \mathrm{R}$ defined as $\mathrm{f}(\mathrm{x})=\mathrm{x}^{3}$ bijective?

## Function Composition

- Let $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ and $\mathrm{g}: \mathrm{T} \rightarrow \mathrm{U}$ denote two functions. Then, the composition function, g o f is a function from S to U defined as $(\mathrm{g} \circ \mathrm{f})(\mathrm{s})=\mathrm{g}(\mathrm{f}(\mathrm{s}))$.
- Arbitrary functions cannot be composed; the domains and ranges have to be compatible.
- Let $\mathrm{f}: \mathrm{R} \rightarrow \mathrm{R}$ be defined by $\mathrm{f}(\mathrm{x})=\mathrm{x}^{2}$ and $\mathrm{g}: \mathrm{R} \rightarrow \mathrm{R}$ be defined by $\mathrm{g}(\mathrm{x})=\lfloor x\rfloor$. Compute ( $\mathrm{g} \circ \mathrm{f}$ )(2.3) and ( $\mathrm{f} \circ \mathrm{g}$ ) (2.3). Solution: $(\mathrm{g}$ o f $)(2.3)=\mathrm{g}(\mathrm{f}(2.3))=\mathrm{g}(5.29)=5$.

$$
(\mathrm{fog})(2.3)=\mathrm{f}(\mathrm{~g}(2.3))=\mathrm{f}(2)=22=4
$$

## Function Composition

- The composition of two injective functions is injective. Proof.

Let $f: S \rightarrow T$ and $g: T \rightarrow U$ denote two injective functions.
Let $s_{1}, s_{2} \in S$. We need to show that if $(g \circ f)\left(s_{1}\right)=(g \circ f)\left(s_{2}\right)$, then $s_{1}=s_{2}$. As per the hypothesis,

$$
\begin{aligned}
(g \circ f)\left(s_{1}\right) & =(g \circ f)\left(s_{2}\right) \\
\Rightarrow g\left(f\left(s_{1}\right)\right) & =g\left(f\left(s_{2}\right)\right) \\
\Rightarrow f\left(s_{1}\right) & =f\left(s_{2}\right), \text { since } g \text { is injective } \\
\Rightarrow s_{1} & =s_{2}, \text { since } f \text { is injective } \\
\Rightarrow(g \circ f) \text { is injective } &
\end{aligned}
$$

## Function composition

- The composition of two surjective function is surjective. Proof.

Let $f: S \rightarrow T$ and $g: T \rightarrow U$ denote two onto functions. Consider the composition $(g \circ f): S \rightarrow U$. Pick an arbitrary element $u \in U$. Since $g$ is surjective, there exists a $t \in T$, such that $g(t)=u$. Since $f$ is surjective, there exists an $s \in S$, such that $f(s)=t$. In other words, $(g \circ f)(s)=u$. Since $u$ was arbitrarily chosen, it follows that $(g \circ f)$ is surjective.

- The composition of two bijective functions is a bijective function.

## Inverse Functions

- The function $i_{S}: S \rightarrow S$ which maps each element of $S$ to itself, is called the identity function on $S$.
- Let $\mathrm{f}: \mathrm{S} \rightarrow$ T denote a bijection. Since f is onto, corresponding to every element $\mathrm{t} \in \mathrm{T}$, there is some element $s \in S$, such that $f(s)=t$. Since $f$ is injective, there is only one $s$ such that $\mathrm{f}(\mathrm{s})=\mathrm{t}$. But this could be construed as the existence of a function $g: T \rightarrow S$, i.e., $g(t)=s$. Note that $g$ is also a bijective function! Observe that $(\mathrm{g} \circ \mathrm{f})(\mathrm{s})=\mathrm{g}(\mathrm{f}(\mathrm{s}))=$ $\mathrm{g}(\mathrm{t})=\mathrm{s}$, i.e., $(\mathrm{g} \circ \mathrm{f})=\mathrm{i}_{\mathrm{s}}$. Similarly, $(\mathrm{f} \circ \mathrm{g})=\mathrm{i}_{\mathrm{T}}$.

## Inverse Functions

- Let $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ denote a function; if there exists a function $\mathrm{g}: \mathrm{T}$
$\rightarrow S$, such that $(\mathrm{g} \circ \mathrm{f})=\mathrm{i}_{\mathrm{S}}$ and $(\mathrm{f} \circ \mathrm{g})=\mathrm{i}_{\mathrm{T}}$, then g is called the inverse function of f and denoted by $\mathrm{f}^{-1}$.
- $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{T}$ is a bijection if and only if $\mathrm{f}^{-1}$ exists.
- Example

Find the inverse of $\mathrm{f}: \mathrm{R} \rightarrow \mathrm{R}$ defined as $\mathrm{f}(\mathrm{x})=3 \mathrm{x}+4$.

## Equivalent Sets

- $A$ set $S$ is equivalent to a set $T$, if there is a bijection $f: S \rightarrow T$. Two sets that are equivalent have the same cardinality.
- Do Z and N have the same cardinality?
- Cantor: For any set $\mathrm{S}, \mathrm{S}$ and $\mathrm{P}(\mathrm{S})$ are not equivalent. Proof:
Assume that $S$ and $\mathcal{P}(S)$ are equivalent and let $f$ be a bijection between $S$ and $\mathcal{P}(S)$. Pick $s \in S ; f(s) \in \mathcal{P}(S)$ and hence $f(s)$ is a set containing some members of $S$. Let $X=\{x \in S \mid x \notin f(x)\}$. Since $X \subseteq S, X \in \mathcal{P}(S)$. Therefore, $X=f(y)$, for some $y \in S$, since $f$ is a bijection!
Is $y \in X$ ? If $y \in X$, then $y \notin f(y)=X$ ! If $y \notin X$, then $y \notin f(y)$ and hence, $y \in X$, by the definition of $X$ ! In either case, there is a contradiction, which proves that $S$ and $\mathcal{P}(S)$ are not equivalent.

## Permutation Functions

- A bijection f from a set A to itself is called a permutation function. Note that f has A as both its domain and its range.
- A permutation function represents a reordering of the set. e.g., $A=\{1,2,3,4\}, f=(1234 ; 2314)$
- A cycle in a permutation of the form $\left(a_{1}, a_{2}, \ldots, a_{k}\right)$ represents the fact that element $a_{1}$ is mapped to $a_{2}, a_{2}$ is mapped to $a_{3}, \ldots, a_{k-1}$ is mapped $a_{k}$ and $a_{k}$ is mapped to $a_{1}$. e.g., f above can be represented as (123) o (4).
- A permutation function in which no element is mapped to itself is called a derangement.

## Counting Functions

Let $S$ and $T$ be sets with cardinality $m$ and $n$ respectively. Let $f: S \rightarrow T$ denote a function from $S$ to $T$.
(i) How many functions are possible from $S$ to $T$, assuming no restriction on $f$ ? $n \cdot n \cdot \ldots n=n^{m}$.
(ii) How many functions are possible from $S$ to $T$, assuming that $f$ is injective?
$n \cdot(n-1) \cdot(n-1) \ldots[n-(m-1)]=\frac{n!}{(n-m)!}=P(n, m)$.
(iii) How many functions are possible from $S$ to $T$, assuming that $f$ is surjective? No nice formula or easy answer. We count the number of non-onto functions and subtract this quantity from the total number of functions!

## Order of Magnitude of Functions

- The order theory enables us to compare functions, just as the theory of arithmetic enables us to compare numbers. In case of functions, we are interested in rate of growth, i.e., does function f grow at a faster rate than function g ?
- Note
- Constants do not matter in rate of growth.
- The starting point of measurement does not matter.
- We only care about functions from $\mathrm{R}_{>=0} \rightarrow \mathrm{R}_{>=0}$.
- Example:
- Which function grows faster: $100 \mathrm{x}^{2}$ or $1 / 10^{6} \mathrm{x}^{3}$ ?
- Which function grows faster: $\mathrm{x}^{2}-10$ or $\mathrm{x}+10$ ?

## Order of Magnitude

- Let f and g be functions mapping non-negative reals to nonnegative reals. Then $\mathrm{f}=\mathrm{O}(\mathrm{g})$, if there exist constants c and $\mathrm{n}_{0}$ such that for all $\mathrm{n}>=\mathrm{n}_{0}, \mathrm{f}(\mathrm{x})<=\mathrm{c} \mathrm{g}(\mathrm{x})$.
- Let f and g be functions mapping non-negative reals to nonnegative reals. Then $\mathrm{f}=\Omega(\mathrm{g})$, if there exist constants c and $n_{0}$ such that for all $n>=n_{0}, f(x)>=c g(x)$.
- Let f and g be functions mapping non-negative reals to nonnegative reals. Then $\mathrm{f}=\Theta(\mathrm{g})$, if $\mathrm{f}=\mathrm{O}(\mathrm{g})$ and $\mathrm{g}=\mathrm{O}(\mathrm{f})$.
- If $\mathrm{f}=\mathrm{O}(\mathrm{g})$, either $\mathrm{f}=\Theta(\mathrm{g})$ or $\mathrm{f}=\mathrm{O}(\mathrm{g})$. If $\mathrm{f}=\Omega(\mathrm{g})$, either f $=\Theta(\mathrm{g})$ or $\mathrm{g}=\mathrm{O}(\mathrm{f})$.

## Examples

- Let $\mathrm{f}(\mathrm{x})=2 \mathrm{x}^{2}-2$ and $\mathrm{g}(\mathrm{x})=1 / 100 \mathrm{x}^{2}-100 . \mathrm{f}=\Theta(\mathrm{g})$.
- Let $\mathrm{f}(\mathrm{x})=2 \mathrm{x}^{2}-2$ and $\mathrm{g}(\mathrm{x})=1 / 100 \mathrm{x}-100$. $\mathrm{f}=\Omega(\mathrm{g})$.
- Let $\mathrm{f}(\mathrm{x})=2 \mathrm{x}^{2}-2$ and $\mathrm{g}(\mathrm{x})=1 / 100 \mathrm{x}-100 . \mathrm{g}=\mathrm{O}(\mathrm{f})$.

## Test to determine order

Let $f$ and $g$ denote two functions mapping non-negative reals to non-negative reals. Let $I=\lim _{x \rightarrow \infty} \frac{f(x)}{g(x)}$. Then
(i) If $/$ is a positive constant, then $f=\Theta(g)$.
(ii) If $I=0$, then $f=o(g)$.
(iii) If $I=\infty$, then $g=o(f)$.

If $\lim _{x \rightarrow \infty} f(x)=\infty$ and if $\lim _{x \rightarrow \infty} g(x)=\infty$, then

$$
\lim _{x \rightarrow \infty} \frac{f(x)}{g(x)}=\lim _{x \rightarrow \infty} \frac{f^{\prime}(x)}{g^{\prime}(x)}
$$

The above rule is called L'Hospital's rule.

- Show that $\mathrm{x}=\mathrm{O}\left(\mathrm{x}^{2}\right)$.
- Show that $\mathrm{x}=\mathrm{O}(\mathrm{x} \log \mathrm{x})$.
- Show that $\log x=O(x)$.
