

Intel® Pentium® 4 Processor with 512-KB L2 Cache on 0.13 Micron Process at 2 GHz, 2.20 GHz, 2.26 GHz, 2.40 GHz, and 2.53 GHz

Datasheet

Product Features

- Available at 2 GHz, 2.20 GHz, 2.26 GHz, 2.40 GHz, and 2.53 GHz
- Binary compatible with applications running on previous members of the Intel microprocessor line
- Intel® NetBurst™ microarchitecture
- System bus frequency at 400 MHz and 533 MHz
- Rapid Execution Engine: Arithmetic Logic Units (ALUs) run at twice the processor core frequency
- Hyper Pipelined Technology
 - Advance Dynamic Execution
 - Very deep out-of-order execution
- Enhanced branch prediction
- Level 1 Execution Trace Cache stores 12-K micro-ops and removes decoder latency from main execution loops
- 8-KB Level 1 data cache
- 512-KB Advanced Transfer Cache (on-die, full-speed Level 2 (L2) cache) with 8-way associativity and Error Correcting Code (ECC)
- 144 Streaming SIMD Extensions 2 (SSE2) instructions
- Enhanced floating point and multimedia unit for enhanced video, audio, encryption, and 3D performance
- Power Management capabilities
 - System Management mode
 - Multiple low-power states
- Optimized for 32-bit applications running on advanced 32-bit operating systems
- 8-way cache associativity provides improved cache hit rate on load/store operations

The Intel® Pentium® 4 processor with 512KB L2 cache on 0.13 micron process is designed for high-performance desktops and entry level workstations. It is binary compatible with previous Intel Architecture processors. The Pentium 4 processor provides great performance for applications running on advanced operating systems such as Microsoft Windows® 98, Windows® Me, Windows® 2000, Windows® XP, and UNIX. This is achieved by the Intel NetBurst microarchitecture, which brings a new level of performance for system buyers. The Pentium 4 processor extends the power of the Pentium III processor with performance headroom for advanced audio and video internet capabilities. Systems based on Pentium 4 processors also include the latest features to simplify system management and lower the total cost of ownership for large and small business environments. The Pentium 4 processor offers great performance for today's and tomorrow's applications.

1.0 Introduction

The Intel® Pentium® 4 processor with 512-KB L2 cache on 0.13 micron process is a follow on to the Pentium 4 processor in the 478-pin package with Intel® NetBurst™ microarchitecture. The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process utilizes Flip-Chip Pin Grid Array (FC-PGA2) package technology, and plugs into a 478-pin surface mount, Zero Insertion Force (ZIF) socket, referred to as the mPGA478B socket. The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process, like its predecessor, the Pentium 4 processor in the 478-pin package, is based on the same Intel 32-bit microarchitecture and maintains the tradition of compatibility with IA-32 software. In this document, the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process will be referred to as the “Pentium 4 processor with 512-KB L2 cache on 0.13 micron process,” or simply “the processor.”

The Intel NetBurst microarchitecture features include hyper pipelined technology, a rapid execution engine, a 400-MHz or a 533-MHz system bus, and an execution trace cache. The hyper pipelined technology doubles the pipeline depth in the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process, allowing the processor to reach much higher core frequencies. The rapid execution engine allows the two integer ALUs in the processor to run at twice the core frequency, which allows many integer instructions to execute in 1/2 clock tick. The 400-MHz or 533-MHz system bus is a quad-pumped bus running off a 100-MHz or a 133-MHz system clock making 3.2 Gbytes/sec and 4.3 Gbytes/sec data transfer rates possible. The execution trace cache is a first-level cache that stores approximately 12-k decoded micro-operations, which removes the instruction decoding logic from the main execution path, thereby increasing performance.

Additional features within the Intel NetBurst microarchitecture include advanced dynamic execution, advanced transfer cache, enhanced floating point and multi-media unit, and Streaming SIMD Extensions 2 (SSE2). The advanced dynamic execution improves speculative execution and branch prediction internal to the processor. The advanced transfer cache is a 512 KB, on-die level 2 (L2) cache. A new floating point and multi media unit has been implemented which provides superior performance for multi-media and mathematically intensive applications. Finally, SSE2 adds 144 new instructions for double-precision floating point, SIMD integer, and memory management. Power management capabilities such as AutoHALT, Stop-Grant, Sleep, and Deep Sleep have been retained.

The Streaming SIMD Extensions 2 (SSE2) enable break-through levels of performance in multimedia applications including 3-D graphics, video decoding/encoding, and speech recognition. The new packed double-precision floating-point instructions enhance performance for applications that require greater range and precision, including scientific and engineering applications and advanced 3-D geometry techniques, such as ray tracing.

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process Intel NetBurst microarchitecture system bus utilizes a split-transaction, deferred reply protocol like the Pentium 4 processor. This system bus is not compatible with the P6 processor family bus. The Intel NetBurst microarchitecture system bus uses Source-Synchronous Transfer (SST) of address and data to improve performance by transferring data four times per bus clock (4X data transfer rate, as in AGP 4X). Along with the 4X data bus, the address bus can deliver addresses two times per bus clock and is referred to as a “double-clocked” or 2X address bus. Working together, the 4X data bus and 2X address bus provide a data bus bandwidth of up to 4.3 Gbytes/second.

Intel will enable support components for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process including heatsinks, heatsink retention mechanisms, and sockets. Manufacturability is a high priority; hence, mechanical assembly can be completed from the top of the motherboard and should not require any special tooling.

The processor system bus uses a variant of GTL+ signalling technology called Assisted Gunning Transceiver Logic (AGTL+) signal technology.

1.1 Terminology

A '#' symbol after a signal name refers to an active low signal, indicating a signal is in the active state when driven to a low level. For example, when RESET# is low, a reset has been requested. Conversely, when NMI is high, a nonmaskable interrupt has occurred. In the case of signals where the name does not imply an active state but describes part of a binary sequence (such as *address* or *data*), the '#' symbol implies that the signal is inverted. For example, D[3:0] = 'HLHL' refers to a hex 'A', and D[3:0]# = 'LHLH' also refers to a hex 'A' (H= High logic level, L= Low logic level).

"System Bus" refers to the interface between the processor and system core logic (a.k.a. the chipset components). The system bus is a multiprocessing interface to processors, memory, and I/O.

1.1.1 Processor Packaging Terminology

Commonly used terms are explained here for clarification:

- **Intel Pentium 4 processor in the 478-pin package** (also referred to as Pentium 4 processor in the 478-pin package) — 0.18-micron Pentium 4 processor core in the FC-PGA2 package.
- **Intel Pentium 4 processor in the 423-pin package** (also referred to as Pentium 4 processor in the 423-pin package)— 0.18-micron Pentium 4 processor core in the PGA package.
- **Intel Pentium 4 processor with 512-KB L2 cache on 0.13 micron process** (also referred to as Pentium 4 processor with 512-KB L2 cache on 0.13 micron process) — 0.13 micron version of Pentium 4 processor in the 478-pin package core in the FC-PGA2 package with a 512-KB L2 cache.
- **Processor** — For this document, the term processor shall mean Pentium 4 processor with 512-KB L2 cache on 0.13 micron process in the 478-pin package.
- **Keep-out zone** — The area on or near the processor that system design can not utilize. This area must be kept free of all components to make room for the processor package, retention mechanism, heatsink, and heatsink clips.
- **Intel® 850 chipset**— chipset which supports Rambus RDRAM* memory technology for Pentium 4 processor with 512-KB L2 cache on 0.13 micron process and Pentium 4 processor in the 478-pin package.
- **Intel® 845 chipset** — chipset which supports PC133 and DDR memory technologies for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process and Pentium 4 processor in the 478-pin package.
- **Processor core** — Pentium 4 processor with 512-KB L2 cache on 0.13 micron process core die with integrated L2 cache.

- **FC-PGA2 package** — Flip-Chip Pin Grid Array package with 50-mil pin pitch and integrated heat spreader.
- **mPGA478B socket** — surface mount, 478 pin, Zero Insertion Force (ZIF) socket with 50 mil pin pitch. Mates the processor to the system board.
- **Integrated heat spreader** — The surface used to make contact between a heatsink or other thermal solution and the processor. Abbreviated IHS.
- **Retention mechanism** — The structure mounted on the system board which provides support and retention of the processor heatsink.

2.0 Electrical Specifications

2.1 System Bus and GTLREF

Most Pentium 4 processor with 512-KB L2 cache on 0.13 micron process system bus signals use Assisted Gunning Transceiver Logic (AGTL+) signalling technology. As with the P6 family of microprocessors, this signalling technology provides improved noise margins and reduced ringing through low voltage swings and controlled edge rates. Like the Pentium 4 processor in the 478-pin package, the termination voltage level for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process AGTL+ signals is V_{CC} , which is the operating voltage of the processor core. The use of a termination voltage that is determined by the processor core allows better voltage scaling on the system bus for Pentium 4 processor with 512-KB L2 cache on 0.13 micron process. Because of the speed improvements to data and address bus, signal integrity and platform design methods have become more critical than with previous processor families. Design guidelines for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process system bus are detailed in the appropriate Platform Design Guide (refer to [Table 1](#)).

The AGTL+ inputs require a reference voltage (GTLREF) which is used by the receivers to determine if a signal is a logical 0 or a logical 1. GTLREF must be generated on the system board.

Termination resistors are provided on the processor silicon and are terminated to its core voltage (V_{CC}). The Intel 850 and the Intel 845 chipsets will also provide on-die termination, thus eliminating the need to terminate the bus on the system board for most AGTL+ signals. However, some AGTL+ signals do not include on-die termination and must be terminated on the system board. For more information, refer to the appropriate Platform Design Guide.

The AGTL+ bus depends on incident wave switching. Therefore timing calculations for AGTL+ signals are based on flight time as opposed to capacitive deratings. Analog signal simulation of the system bus, including trace lengths, is highly recommended when designing a system. For more information, refer to the appropriate Platform Design Guide.

2.2 Power and Ground Pins

For clean on-chip power distribution, the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process has 85 V_{CC} (power) and 181 V_{SS} (ground) inputs. All power pins must be connected to V_{CC} , while all V_{SS} pins must be connected to a system ground plane. The processor V_{CC} pins must be supplied with the voltage defined by the VID (Voltage ID) pins and the loadline specifications (see [Figure 4](#)).

2.3 Decoupling Guidelines

Due to the large number of transistors and high internal clock speeds, the processor is capable of generating large average current swings between low and full power states. This may cause voltages on power planes to sag below their minimum values if bulk

decoupling is not adequate. Care must be taken in the board design to ensure that the voltage provided to the processor remains within the specifications listed in [Table 7](#). Failure to do so can result in timing violations and/or affect the long term reliability of the processor. For further information and design guidelines, refer to the appropriate Platform Design Guide and the *Intel® Pentium® 4 Processor VR-Down Design Guidelines*.

2.3.1 V_{CC} Decoupling

Regulator solutions need to provide bulk capacitance with a low Effective Series Resistance (ESR) and keep a low interconnect resistance from the regulator to the socket. Bulk decoupling for the large current swings when the part is powering on, or entering/exiting low power states, must be provided by the voltage regulator solution (VR). For more details on this topic, refer to the appropriate Platform Design Guide and the *Intel® Pentium® 4 Processor VR-Down Design Guidelines*.

2.3.2 System Bus AGTL+ Decoupling

Pentium 4 processors with 512-KB L2 cache on 0.13 micron process integrate signal termination on the die as well as incorporate high frequency decoupling capacitance on the processor package. Decoupling must also be provided by the system motherboard for proper AGTL+ bus operation. For more information, refer to the appropriate Platform Design Guide.

2.4 Voltage Identification

The VID specification for Pentium 4 processors with 512-KB L2 cache on 0.13 micron process is supported by the *Intel® Pentium® 4 Processor VR-Down Design Guidelines*. The voltage set by the VID pins is the maximum voltage allowed by the processor. A minimum voltage is provided in [Table 7](#) and changes with frequency. This allows processors running at a higher frequency to have a relaxed minimum voltage specification. The specifications have been set such that one voltage regulator can work with all supported frequencies.

Pentium 4 processors with 512-KB L2 cache on 0.13 micron process use five voltage identification pins, VID[4:0], to support automatic selection of power supply voltages. The VID pins for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process are open drain outputs driven by the processor VID circuitry. The VID signals rely on pull-up resistors tied to a 3.3V (max) supply to set the signal to a logic high level. These pull-up resistors may be either external logic on the motherboard or internal to the Voltage Regulator. [Table 3](#) specifies the voltage level corresponding to the state of VID[4:0]. A '1' in this table refers to a high voltage level and a '0' refers to low voltage level. The definition provided in [Table 3](#) is not related in any way to previous P6 processors or VRs, but is compatible with the Pentium 4 processor in the 478-pin package. If the processor socket is empty (VID[4:0] = 11111), or the voltage regulation circuit cannot supply the voltage that is requested, it must disable itself. See the *Intel® Pentium® 4 Processor VR-Down Design Guidelines* for more details.

Power source characteristics must be stable whenever the supply to the voltage regulator is stable. Refer to the appropriate Platform Design Guide for timing details of the power up sequence. Refer to the appropriate Platform Design Guide for implementation details.

The Voltage Identification circuit requires an independent 1.2 V supply. This voltage must be routed to the processor VCCVID pin. [Figure 1](#) and [Table 2](#) show the voltage and current requirements of the VCCVID pin.

Table 2. VCCVID Pin Voltage Requirements

Symbol	Parameter	Min	Typ	Max	Unit	Notes
VCCVID	Vcc for voltage identification circuit	-5%	1.2	+10%	V	1

NOTES:

1. This specification applies to both static and transient components. The rising edge of VCCVID must be monotonic from 0 to 1.1 V. See [Figure 1](#) for current requirements. In this case, monotonic is defined as continuously increasing with less than 50mV of peak to peak noise for any width greater than 2 ns superimposed on the rising edge.

Figure 1. VCCVID Pin Voltage and Current Requirements

Table 3. Voltage Identification Definition

Processor Pins					
VID4	VID3	VID2	VID1	VID0	V _{CC_MAX}

0	1	1	0	1	1.525
0	1	1	0	0	1.550

2.4.1 Phase Lock Loop (PLL) Power and Filter

V_{CCA} and V_{CCIOPLL} are power sources required by the PLL clock generators on the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process. Since these PLLs are analog in nature, they require quiet power supplies for minimum jitter. Jitter is detrimental to the system; it degrades external I/O timings as well as internal core timings (i.e., maximum frequency). To prevent this degradation, these supplies must be low pass filtered from V_{CC}. A typical filter topology is shown in [Figure 2](#).

The AC low-pass requirements, with input at V_{CC} and output measured across the capacitor (C_A or C_{IO} in [Figure 2](#)), is as follows:

- < 0.2 dB gain in pass band
- < 0.5 dB attenuation in pass band < 1 Hz
- > 34 dB attenuation from 1 MHz to 66 MHz
- > 28 dB attenuation from 66 MHz to core frequency

Refer to the appropriate Platform Design Guide for recommendations on implementing the filter.

Figure 2. Typical $V_{CCIOPLL}$, V_{CCA} and V_{SSA} Power Distribution

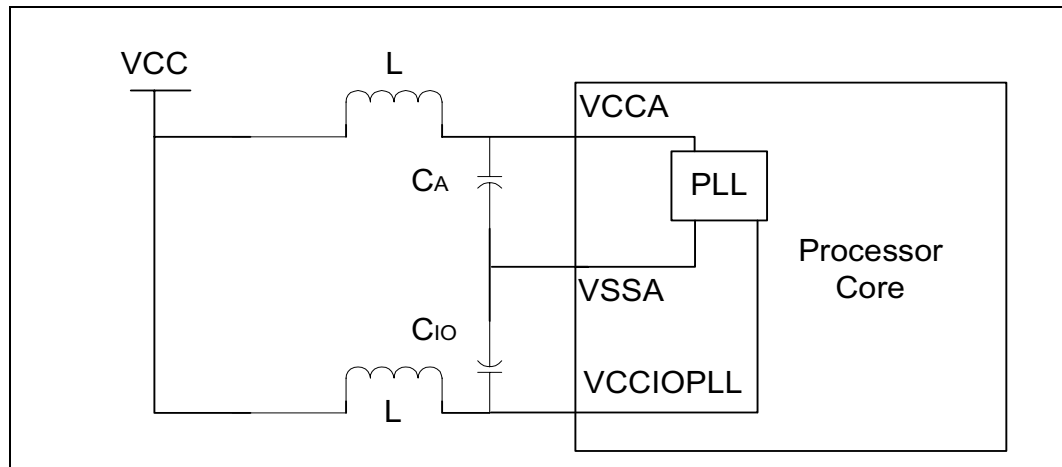

Figure 3. Phase Lock Loop (PLL) Filter Requirements

NOTES:

1. Diagram not to scale.
2. No specification for frequencies beyond f_{core} (core frequency).
3. f_{peak} , if existent, should be less than 0.05 MHz.

2.5 Reserved, Unused Pins, and TESTHI[12:0]

All RESERVED pins must remain unconnected. Connection of these pins to V_{CC} , V_{SS} , or to any other signal (including each other) can result in component malfunction or incompatibility with future Pentium 4 processors with 512-KB L2 cache on 0.13 micron process. See [Chapter 4.0](#) for a pin listing of the processor and the location of all RESERVED pins.

For reliable operation, always connect unused inputs or bidirectional signals that are not terminated on the die to an appropriate signal level. Note that on-die termination has been included on the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process to allow signals to be terminated within the processor silicon. Unused active low AGTL+ inputs may be left as no connects if AGTL+ termination is provided on the processor silicon. [Table 4](#) lists details on AGTL+ signals that do not include on-die termination. Unused active high inputs should be connected through a resistor to ground (V_{SS}). Refer to the appropriate Platform Design Guide for the appropriate resistor values.

Unused outputs can be left unconnected, however, this may interfere with some TAP functions, complicate debug probing, and prevent boundary scan testing. A resistor must be used when tying bidirectional signals to power or ground. When tying any signal to power or ground, a resistor will also allow for system testability. For unused AGTL+ input or I/O signals that don't have on-die termination, use pull-up resistors of the same value in place of the on-die termination resistors (R_{TT}). See [Table 14](#).

The TAP, Asynchronous GTL+ inputs, and Asynchronous GTL+ outputs do not include on-die termination. Inputs and used outputs must be terminated on the system board. Unused outputs may be terminated on the system board or left unconnected. Note that leaving unused output unterminated may interfere with some TAP functions, complicate debug probing, and prevent boundary scan testing. Signal termination for these signal types is discussed in the appropriate Platform Design Guide in [Table 1](#).

The TESTHI pins should be tied to the processor V_{CC} using a matched resistor, where a matched resistor has a resistance value within $\pm 20\%$ of the impedance of the board transmission line traces. For example, if the trace impedance is 50 Ω , then a value between 40 Ω and 60 Ω is required.

The TESTHI pins may use individual pull-up resistors or be grouped together as detailed below. A matched resistor should be used for each group:

1. TESTHI[1:0]
2. TESTHI[5:2]
3. TESTHI[10:8]
4. TESTHI[12:11]

Additionally, if the ITPCLKOUT[1:0] pins are not used then they may be connected individually to V_{CC} using matched resistors or grouped with TESTHI[5:2] with a single matched resistor. If they are being used, individual termination with 1 k Ω resistors is required. Tying ITPCLKOUT[1:0] directly to V_{CC} or sharing a pull-up resistor to V_{CC} will prevent use of debug interposers. This implementation is strongly discouraged for system boards that do not implement an inboard debug port.

As an alternative, group2 (TESTHI[5:2]), and the ITPCLKOUT[1:0] pins may be tied directly to the processor V_{CC} . This has no impact on system functionality. TESTHI[0] and TESTHI[12] may also be tied directly to the processor V_{CC} if resistor termination is a problem, but matched resistor termination is recommended. In the case of the ITPCLKOUT[1:0] pins, direct tie to V_{CC} is strongly discouraged for system boards that do not implement an inboard debug port.

Tying any of the TESTHI pins together will prevent the ability to perform boundary scan testing.

2.6 System Bus Signal Groups

In order to simplify the following discussion, the system bus signals have been combined into groups by buffer type. AGTL+ input signals have differential input buffers, which use GTLREF as a reference level. In this document, the term "AGTL+ Input" refers to the AGTL+ input group as well as the AGTL+ I/O group when receiving. Similarly, "AGTL+ Output" refers to the AGTL+ output group as well as the AGTL+ I/O group when driving.

With the implementation of a source synchronous data bus comes the need to specify two sets of timing parameters. One set is for common clock signals which are dependent upon the rising edge of BCLK0 (ADS#, HIT#, HITM#, etc.) and the second set is for the source synchronous signals which are relative to their respective strobe lines (data and address) as well as the rising edge of BCLK0. Asynchronous signals are still present (A20M#, IGNNE#, etc.) and can become active at any time during the clock cycle. Table 4 identifies which signals are common clock, source synchronous, and asynchronous.

Table 4. System Bus Pin Groups (Sheet 1 of 2)

Signal Group	Type	Signals ¹														
AGTL+ Common Clock Input	Common Clock	BPRI#, DEFER#, RESET# ² , RS[2:0]#, RSP#, TRDY#														
AGTL+ Common Clock I/O	Synchronous	AP[1:0]#, ADS#, BINIT#, BNR#, BPM[5:0]# ² , BR0# ² , DBSY#, DP[3:0]#, DRDY#, HIT#, HITM#, LOCK#, MCERR#														
AGTL+ Source Synchronous I/O	Source Synchronous	<table><tr><th>Signals</th><th>Associated Strobe</th></tr><tr><td>REQ[4:0]#, A[16:3]#⁵</td><td>ADSTB0#</td></tr><tr><td>A[35:17]#⁵</td><td>ADSTB1#</td></tr><tr><td>D[15:0]#, DBI0#</td><td>DSTBP0#, DSTBN0#</td></tr><tr><td>D[31:16]#, DBI1#</td><td>DSTBP1#, DSTBN1#</td></tr><tr><td>D[47:32]#, DBI2#</td><td>DSTBP2#, DSTBN2#</td></tr><tr><td>D[63:48]#, DBI3#</td><td>DSTBP3#, DSTBN3#</td></tr></table>	Signals	Associated Strobe	REQ[4:0]#, A[16:3]# ⁵	ADSTB0#	A[35:17]# ⁵	ADSTB1#	D[15:0]#, DBI0#	DSTBP0#, DSTBN0#	D[31:16]#, DBI1#	DSTBP1#, DSTBN1#	D[47:32]#, DBI2#	DSTBP2#, DSTBN2#	D[63:48]#, DBI3#	DSTBP3#, DSTBN3#
Signals	Associated Strobe

Asynchronous GTL+ Input ^{4,5}	Asynchronous	A20M#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, SMI#, SLP#, STPCLK#														
Asynchronous GTL+ Output ⁴	Asynchronous	FERR#, IERR# ² , THERMTRIP#, PROCHOT#														

Table 4. System Bus Pin Groups (Sheet 2 of 2)

Signal Group	Type	Signals ¹
TAP Input ⁴	Synchronous to TCK	TCK, TDI, TMS, TRST#
TAP Output ⁴	Synchronous to TCK	TDO
System Bus Clock	N/A	BCLK[1:0], ITP_CLK[1:0] ³
Power/Other	N/A	V _{CC} , V _{CCA} , V _{CCIOPLL} , VCCVID, VID[4:0], V _{SS} , V _{SSA} , GTLREF[3:0], COMP[1:0], RESERVED, TESTHI[5:0, 12:8], ITPCLKOUT[1:0], THERMDA, THERMDC, PWRGOOD, SKTOCC#, V _{CC_SENSE} , V _{SS_SENSE} , BSEL[1:0], DBR# ³

NOTES:

1. Refer to [Section 4.2](#) for signal descriptions.
2. These AGTL+ signals do not have on-die termination. Refer to [Section 2.5](#) and the *ITP 700 Debug Port Design Guide* for termination requirements.
3. In processor systems where there is no debug port implemented on the system board, these signals are used to support a debug port interposer. In systems with the debug port implemented on the system board, these signals are no connects.
4. These signal groups are not terminated by the processor. Refer to [Section 2.5](#), the *ITP 700 Debug Port Design Guide*, and the appropriate Platform Design Guide for termination requirements and further details.
5. The value of these pins during the active-to-inactive edge of RESET# defines the processor configuration options. See [Section 6.1](#) for details.

2.7 Asynchronous GTL+ Signals

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process does not utilize CMOS voltage levels on any signals that connect to the processor. As a result, legacy input signals such as A20M#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, PWRGOOD, SMI#, SLP#, and STPCLK# utilize GTL+ input buffers. Legacy output FERR# and other non-AGTL+ signals (THERMTRIP# and PROCHOT#) utilize GTL+ output buffers. All of these signals follow the same DC requirements as AGTL+ signals, however the outputs are not actively driven high (during a logical 0 to 1 transition) by the processor (the major difference between GTL+ and AGTL+). These signals do not have setup or hold time specifications in relation to BCLK[1:0]. However, all of the Asynchronous GTL+ signals are required to be asserted for at least two BCLKs in order for the processor to recognize them. See [Section 2.11](#) for the DC specifications for the Asynchronous GTL+ signal groups. See [Section 6.2](#) for additional timing requirements for entering and leaving the low power states.

2.8 Test Access Port (TAP) Connection

Due to the voltage levels supported by other components in the Test Access Port (TAP) logic, it is recommended that the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process be first in the TAP chain and followed by any other components within the system. A translation buffer should be used to connect to the rest of the chain unless one of the other components is capable of accepting an input of the appropriate voltage level. Similar considerations must be made for TCK, TMS, and TRST#. Two copies of each signal may be required, with each driving a different voltage level.

2.9 System Bus Frequency Select Signals (BSEL[1:0])

The BSEL[1:0] are output signals used to select the frequency of the processor input clock (BCLK[1:0]). [Table 5](#) defines the possible combinations of the signals and the frequency associated with each combination. The required frequency is determined by the processor, chipset, and clock synthesizer. All agents must operate at the same frequency.

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process currently operates at a 400 MHz or 533 MHz system bus frequency. Individual processors will only operate at their specified system bus frequency.

For more information about these pins refer to [Section 4.2](#) and the appropriate platform design guidelines.

Table 5. BSEL[1:0] Frequency Table for BCLK[1:0]

BSEL1	BSEL0	Function
L	L	100 MHz
L	H	133 MHz
H	L	RESERVED
H	H	RESERVED

2.10 Maximum Ratings

[Table 6](#) lists the processor's maximum environmental stress ratings. The processor should not receive a clock while subjected to these conditions. Functional operating parameters are listed in the DC tables. Extended exposure to the maximum ratings may affect device reliability. Furthermore, although the processor contains protective circuitry to resist damage from Electro Static Discharge (ESD), one should always take precautions to avoid high static voltages or electric fields.

Table 6. Processor DC Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Unit	Notes
T_{STORAGE}	Processor storage temperature	-40	85	°C	2
V_{CC}	Any processor supply voltage with respect to V_{SS}	-0.3	1.75	V	1
$V_{\text{inAGTL+}}$	AGTL+ buffer DC input voltage with respect to V_{SS}	-0.1	1.75	V	
$V_{\text{inAsynch_GTL+}}$	Asynch GTL+ buffer DC input voltage with respect to V_{SS}	-0.1	1.75	V	
I_{VID}	Max VID pin current		5	mA	

NOTES:

1. This rating applies to any processor pin.
2. Contact Intel for storage requirements in excess of one year.

2.11 Processor DC Specifications

The processor DC specifications in this section are defined at the processor core silicon unless noted otherwise. See Chapter 5.0 for the pin signal definitions and signal pin assignments. Most of the signals on the processor system bus are in the AGTL+ signal group. The DC specifications for these signals are listed in [Table 9](#).

Previously, legacy signals and Test Access Port (TAP) signals to the processor used low-voltage CMOS buffer types. However, these interfaces now follow DC specifications similar to GTL+. The DC specifications for these signal groups are listed in [Table 10](#).

[Table 7](#) through [Table 10](#) list the DC specifications for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process, and are valid only while meeting specifications for case temperature, clock frequency, and input voltages. Care should be taken to read all notes associated with each parameter.

Table 7. Voltage and Current Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Notes ¹⁰
V_{CC}	V _{CC} for Processor at VID=1.500V:		Refer to Table 8 and Figure 4		V	1, 2, 3, 4, 8
	2 GHz	1.340				
	2.20 GHz	1.335				
	2.26 GHz	1.330				
	2.40 GHz	1.330				
	2.53 GHz	1.325				
VCCVID	V _{CC} for voltage identification circuit	-5%	1.2	+10%	V	9
I_{CC}	I_{CC} for Processor at VID=1.500V:				A	3, 4, 6, 8
	2 GHz			44.3		
	2.20 GHz			47.1		
	2.26 GHz			48.0		
	2.40 GHz			49.8		
	2.53 GHz			51.5		
I_{SGNT} I_{slp}	I_{CC} Stop-Grant			18	A	7, 5
I_{TCC}	I_{CC} TCC active			I_{CC}	A	7
I_{CC_PLL}	I_{CC} for PLL pins			60	mA	

NOTES:

- These voltages are targets only. A variable voltage source should exist on systems in the event that a different voltage is required. See Table 3 for more information. The VID bits will set the maximum V_{CC} with the minimum being defined according to current consumption at that voltage.
- The voltage specification requirements are measured across $V_{CCSENSE}$ and $V_{SSSENSE}$ pins at the socket with a 100MHz bandwidth oscilloscope, 1.5 pF maximum probe capacitance, and 1 M Ω minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled in the scope probe.
- Refer to Table 8 and Figure 4 for the minimum, typical, and maximum V_{CC} allowed for a given current. The processor should not be subjected to any V_{CC} and I_{CC} combination wherein V_{CC} exceeds V_{CC_MAX} for a given current. Moreover, V_{CC} should never exceed the VID voltage. Failure to adhere to this specification can affect the long term reliability of the processor.
- V_{CC_MIN} is defined at I_{CC_MAX} .
- The current specified is also for AutoHALT State.
- The maximum instantaneous current the processor will draw while the thermal control circuit is active as indicated by the assertion of PROCHOT# is the same as the maximum I_{CC} for the processor.
- I_{CC} Stop-Grant and I_{CC} Sleep are specified at V_{CC_MAX} .
- These specifications apply to processor with VID setting of 1.500 V.
- This specification applies to both static and transient components. The rising edge of VCCVID must be monotonic from 0 to 1.1 V. See Figure 1 for current requirements. In this case monotonic is defined as continuously increasing with less than 50 mV of peak to peak noise for any width greater than 2 ns superimposed on the rising edge.

Table 8. V_{CC} Static and Transient Tolerance

I _{CC} (A)	Voltage Deviation from VID Setting (V) ^{1,2,3}		
	Maximum	Typical	Minimum
0	0.000	-0.025	-0.050
5	-0.010	-0.036	-0.062
10	-0.019	-0.047	-0.075
15	-0.029	-0.058	-0.087
20	-0.038	-0.069	-0.099
25	-0.048	-0.079	-0.111
30	-0.057	-0.090	-0.124
35	-0.067	-0.101	-0.136
40	-0.076	-0.112	-0.148
45	-0.085	-0.123	-0.160
50	-0.095	-0.134	-0.173
55	-0.105	-0.145	-0.185
60	-0.114	-0.156	-0.197
65	-0.124	-0.166	-0.209
70	-0.133	-0.177	-0.222

NOTES:

1. The loadline specifications include both static and transient limits.
2. This table is intended to aid in reading discrete points on the loadline figure below.
3. The loadlines specify voltage limits at the die measured at V_{CCSENSE} and V_{SSSENSE} pins. Voltage regulation feedback for voltage regulator circuits must be taken from processor V_{CC} and V_{SS} pins. Refer to the *Intel® Pentium® 4 Processor VR-Down Design Guidelines* for V_{CC} and V_{SS} socket loadline specifications and VR implementation details.
4. Adherence to this loadline specification for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process is required to ensure reliable processor operation.

Figure 4. V_{CC} Static and Transient Tolerance ($V_{ID} = 1.500\text{ V}$)

NOTES:

1. The loadline specification includes both static and transient limits.
2. This loadline specification applies to processors with a VID setting of 1.500 V.
3. The loadlines specify voltage limits at the die measured at V_{CC_sense} and V_{SS_sense} pins. Voltage regulation feedback for voltage regulator circuits must be taken from processor V_{CC} and V_{SS} pins. Refer to the *Intel® Pentium® 4 Processor VR-Down Design Guidelines* V_{CC} and V_{SS} socket loadline specifications and VR implementation details.
4. Adherence to this loadline specification for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process is required to ensure reliable processor operation.

Table 9. AGTL+ Signal Group DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ¹
GTLREF	Reference Voltage	2/3 V _{CC} - 2%	2/3 V _{CC} + 2%	V	
V _{IH}	Input High Voltage	1.10*GTLREF	V _{CC}	V	2,5
V _{IL}	Input Low Voltage	0.0	0.9*GTLREF	V	3,5
V _{OH}	Output High Voltage	N/A	V _{CC}	V	6
I _{OL}	Output Low Current	N/A	50	mA	5
I _{HI}	Pin Leakage High	N/A	100	μA	7
I _{LO}	Pin Leakage Low	N/A	500	μA	8
R _{ON}	Buffer On Resistance	7	11	Ω	4

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value.
3. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value.
4. Refer to processor I/O Buffer Models for I/V characteristics.
5. The V_{CC} referred to in these specifications is the instantaneous V_{CC}.
6. Vol max of 0.450 Volts is guaranteed when driving into a test load of 50 Ω as indicated in [Figure 6](#).
7. Leakage to Vss with pin held at Vcc.
8. Leakage to Vcc with Pin held at 300 mV.

Table 10. Asynchronous GTL+ Signal Group DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ¹
V _{IH}	Input High Voltage Asynch GTL+	1.10*GTLREF	V _{CC}	V	3, 4
V _{IL}	Input Low Voltage Asynch. GTL+	0	0.9*GTLREF	V	4
V _{OH}	Output High Voltage		V _{CC}	V	2, 3
I _{OL}	Output Low Current		50	mA	5, 7
I _{HI}	Pin Leakage High	N/A	100	μA	8
I _{LO}	Pin Leakage Low	N/A	500	μA	9
R _{on}	Buffer On Resistance Asynch GTL+	7	11	Ω	4,6

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. All outputs are open-drain.
3. The V_{CC} referred to in these specifications refers to instantaneous V_{CC}.
4. This specification applies to the asynchronous GTL+ signal group.
5. The maximum output current is based on maximum current handling capability of the buffer and is not specified into the test load shown in [Figure 6](#).
6. Refer to the processor I/O Buffer Models for I/V characteristics.
7. Vol max of 0.270 Volts is guaranteed when driving into a test load of 50Ω as indicated in [Figure 6](#) for the Asynchronous GTL+ signals.
8. Leakage to Vss with pin held at Vcc.
9. Leakage to Vcc with Pin held at 300 mV.

Table 11. PWRGOOD and TAP Signal Group DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ¹
V _{HYS}	Input Hysteresis	200	300	mV	6
V _{T+}	Input Low to High Threshold Voltage	$1/2 \cdot (V_{CC} + V_{HYS_MIN})$	$1/2 \cdot (V_{CC} + V_{HYS_MAX})$	V	4
V _{T-}	Input High to Low Threshold Voltage	$1/2 \cdot (V_{CC} - V_{HYS_MAX})$	$1/2 \cdot (V_{CC} - V_{HYS_MIN})$	V	5
V _{OH}	Output High Voltage	N/A	V _{CC}	V	2,3,4
I _{OL}	Output Low Current	N/A	40	mA	5,6
I _{HI}	Pin Leakage High	N/A	100	μA	8
I _{LO}	Pin Leakage Low	N/A	500	μA	9
R _{ON}	Buffer On Resistance	8.75	13.75	Ω	3

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. All outputs are open-drain.
3. Refer to I/O Buffer Models for I/V characteristics.
4. The V_{CC} referred to in these specifications refers to instantaneous V_{CC}.
5. The maximum output current is based on maximum current handling capability of the buffer and is not specified into the test load shown in Figure 6.
6. Vol max of 0.320 Volts is guaranteed when driving into a test load of 50 Ω as indicated in Figure 6 for the TAP Signals.
7. V_{HYS} represents the amount of hysteresis, nominally centered about 1/2 V_{CC} for all TAP inputs.
8. Leakage to V_{SS} with pin held at V_{CC}.
9. Leakage to V_{CC} with Pin held at 300 mV.

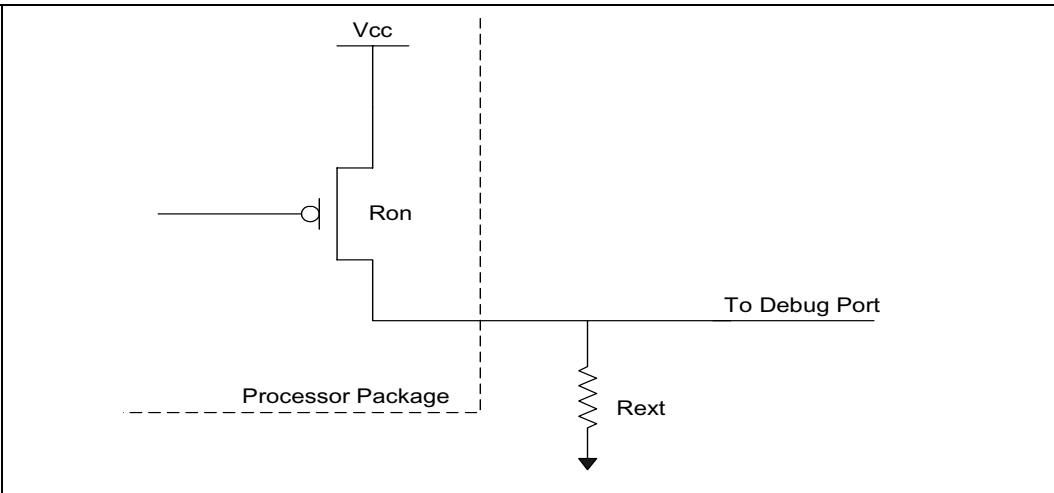

Table 12. ITPCLKOUT[1:0] DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ¹
R _{on}	Buffer On Resistance	27	46	Ω	2,3

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. These parameters are not tested and are based on design simulations.
3. See Figure 5 for ITPCLKOUT[1:0] output buffer diagram.

Figure 5. ITPCLKOUT[1:0] Output Buffer Diagram

- NOTES:**
- 1. See Table 12 for range of Ron.
 - 2. The Vcc referred to in this figure is the instantaneous Vcc.
 - 3. Refer to the *ITP 700 Debug Port Design Guide* and the appropriate platform design guidelines for the value of Rext.

Table 13. BSEL [1:0] and VID[4:0] DC Specifications

Symbol	Parameter	Min	Max	Unit	Notes ¹
Ron (BSEL)	Buffer On Resistance	9.2	14.3	Ω	2
Ron (VID)	Buffer On Resistance	7.8	12.8	Ω	2
I _{HI}	Pin Leakage High	N/A	100	μA	3

- NOTES:**
- 1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
 - 2. These parameters are not tested and are based on design simulations.
 - 3. Leakage to Vss with pin held at 2.50 V.

2.12 AGTL+ System Bus Specifications

Routing topology recommendations may be found in the appropriate Platform Design Guide listed in Table 1. Termination resistors are not required for most AGTL+ signals, as these are integrated into the processor silicon.

Valid high and low levels are determined by the input buffers which compare a signal's voltage with a reference voltage called GTLREF (known as V_{REF} in previous documentation).

Table 14 lists the GTLREF specifications. The AGTL+ reference voltage (GTLREF) should be generated on the system board using high precision voltage divider circuits. It is important that the system board impedance is held to the specified tolerance, and that the intrinsic trace capacitance for the AGTL+ signal group traces is known and well-controlled. For more details on platform design see the appropriate Platform Design Guide.

Table 14. AGTL+ Bus Voltage Definitions

Symbol	Parameter	Min	Typ	Max	Units	Notes ¹
GTLREF	Bus Reference Voltage	$2/3 V_{CC} - 2\%$	$2/3 V_{CC}$	$2/3 V_{CC} + 2\%$	V	2, 3, 6
R_{TT}	Termination Resistance	45	50	55	Ω	4, 7
COMP[1:0]	COMP Resistance	50.49	51	51.51	Ω	5

NOTES:

1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. The tolerances for this specification have been stated generically to enable the system designer to calculate the minimum and maximum values across the range of V_{CC} .
3. GTLREF should be generated from V_{CC} by a voltage divider of 1% tolerance resistors or 1% tolerance, matched resistors. Refer to the appropriate Platform Design Guide for implementation details.
4. R_{TT} is the on-die termination resistance measured at V_{OL} of the AGTL+ output driver. Refer to processor I/O buffer models for I/V characteristics.
5. COMP resistance must be provided on the system board with 1% tolerance resistors. See the appropriate Platform Design Guide for implementation details.
6. The V_{CC} referred to in these specifications is the instantaneous V_{CC} .
7. This value has changed compared to the Pentium 4 processor in the 423-pin package, and will be the same for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process and Pentium 4 processor in the 478-pin package.

Figure 6. Test Circuit

This page is intentionally left blank.

3.0 Package Mechanical Specifications

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process is packaged in a Flip-Chip Pin Grid Array (FC-PGA2) package. Components of the package include an integrated heat spreader (IHS), processor die, and the substrate which is the pin carrier. Mechanical specifications for the processor are given in this section. See [Section 1.1](#) for a terminology listing. The processor socket which accepts the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process is referred to as a 478-Pin micro PGA (mPGA478B) socket. See the *Intel® Pentium® 4 Processor 478-Pin Socket (mPGA478B) Socket Design Guidelines* for complete details on the mPGA478B socket.

Note: For [Figure 7](#) through [Figure 13](#), the following notes apply:

1. Unless otherwise specified, the following drawings are dimensioned in millimeters.
2. Figures and drawings labelled as “Reference Dimensions” are provided for informational purposes only. Reference dimensions are extracted from the mechanical design database and are nominal dimensions with no tolerance information applied. Reference dimensions are **not** checked as part of the processor manufacturing process. Unless noted as such, dimensions in parentheses without tolerances are reference dimensions.
3. Drawings are not to scale.

Note: The drawing below is not to scale and is for reference only. The socket and system board are supplied as a reference only.

Figure 7. Exploded View of Processor Components on a System Board

Figure 8. Processor Package

Table 15. Description Table for Processor Dimensions

Code Letter	Dimension (mm)			Notes
	Min	Nominal	Max	
A1	2.266	2.378	2.490	
A2	0.980	1.080	1.180	
B1	30.800	31.000	31.200	
B2	30.800	31.000	31.200

G1			13.970	Keep-In Zone Dimension
G2			13.970	Keep-In Zone Dimension
G3			1.250	Keep-In Zone Dimension
H		1.270		
L	1.950	2.030	2.110	
ØP	0.280	0.305	0.330	
PIN TP			0.254	Diametric True Position (Pin-to-Pin)
IHS Flatness			0.05	

Figure 9 details the keep-in specification for pin-side components. The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process may contain pin side capacitors mounted to the processor package.

Figure 11 details the flatness and tilt specifications for the IHS. Tilt is measured with the reference datum set to the bottom of the processor substrate.

Figure 9. Processor Cross-Section and Keep-In

Figure 10. Processor Pin Detail

NOTES:

1. Pin plating consists of 0.2 micrometers Au over 2.0 micrometer Ni.
2. 0.254 mm diametric true position, pin to pin.

Figure 11. IHS Flatness Specification

**NOTES:**

1. Flatness is specific as overall, not per unit of length.
2. All Dimensions are in millimeters.

3.1 Package Load Specifications

Table 16 provides dynamic and static load specifications for the processor IHS. These mechanical load limits should not be exceeded during heatsink assembly, mechanical stress testing, or standard drop and shipping conditions. The heatsink attach solutions must not induce continuous stress onto the processor with the exception of a uniform load to maintain the heat sink-to-processor thermal interface contact. It is not recommended to use any portion of the processor substrate as a mechanical reference or load bearing surface for thermal solutions.

Table 16. Package Dynamic and Static Load Specifications

Parameter	Max	Unit	Notes
Static	100	lbf	1, 2
Dynamic	200	lbf	1, 3

NOTES:

1. This specification applies to a uniform compressive load.
2. This is the maximum static force that can be applied by the heatsink and clip to maintain the heatsink and processor interface.
3. Dynamic loading specifications are defined assuming a maximum duration of 11 ms and 200 lbf is achieved by superimposing a 100 lbf dynamic load (1 lbf at 50g) on the static compressive load.

3.2 Processor Insertion Specifications

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process can be inserted and removed 15 times from a mPGA478B socket meeting the *Intel® Pentium® 4 Processor 478-Pin Socket (mPGA478B) Socket Design Guidelines* document.

3.3 Processor Mass Specifications

Table 17 specifies the processor's mass. This includes all components which make up the entire processor product.

Table 17. Processor Mass

Processor	Mass (grams)
Intel® Pentium® 4 processor with 512-KB L2 cache on 0.13 micron process	19

3.4 Processor Materials

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process is assembled from several components. The basic material properties are described in Table 18.

Table 18. Processor Material Properties

Component	Material	Notes
Integrated Heat Spreader	Nickel over copper	
Substrate	Fiber-reinforced resin	
Substrate pins	Gold over nickel	

3.5 Processor Markings

The following section details the processor top-side markings and is provided to aid in the identification of the Pentium 4 processors with 512-KB L2 cache on 0.13 micron process. This detail will be provided in a future release of the processor EMTS.

Figure 12. Processor Markings

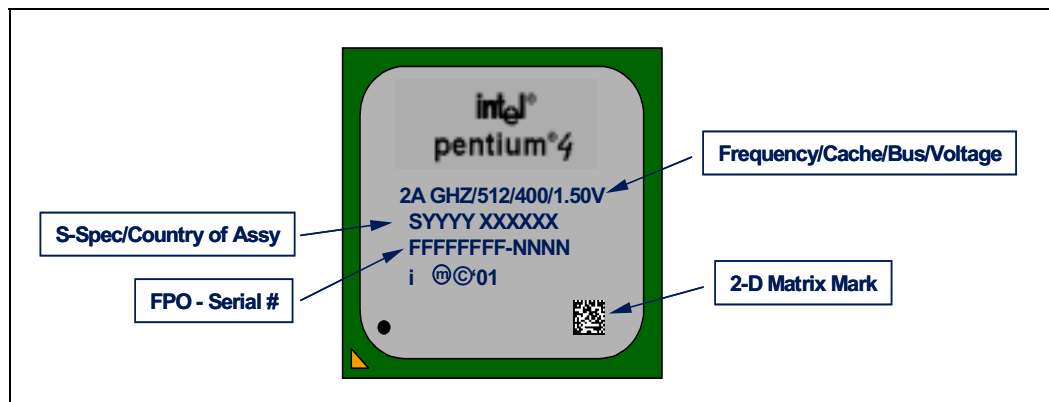

Figure 13. The Coordinates of the Processor Pins As Viewed from the Top of the Package

This page is intentionally left blank.

4.0 Pin Listing and Signal Definitions

4.1 Processor Pin Assignments

Section 4.1 contains the pinlist for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process in [Table 19](#) and [Table 20](#). [Table 19](#) is a listing of all processor pins ordered alphabetically by pin name. [Table 20](#) is also a listing of all processor pins but ordered by pin number.

4.2 Alphabetical Signals Reference

Table 21. Signal Description (Sheet 1 of 8)

Name	Type	Description												
A[35:3]#	Input/ Output	<p>A[35:3]# (Address) define a 2³⁶-byte physical memory address space. In sub-phase 1 of the address phase, these pins transmit the address of a transaction. In sub-phase 2, these pins transmit transaction type information. These signals must connect the appropriate pins of all agents on the Intel® Pentium® 4 processor with 512-KB L2 cache on 0.13 micron process system bus. A[35:3]# are protected by parity signals AP[1:0]#. A[35:3]# are source synchronous signals and are latched into the receiving buffers by ADSTB[1:0]#.</p> <p>On the active-to-inactive transition of RESET#, the processor samples a subset of the A[35:3]# pins to determine power-on configuration. See Section 6.1 for more details.</p>												
A20M#	Input	<p>If A20M# (Address-20 Mask) is asserted, the processor masks physical address bit 20 (A20#) before looking up a line in any internal cache and before driving a read/write transaction on the bus. Asserting A20M# emulates the 8086 processor's address wrap-around at the 1-Mbyte boundary. Assertion of A20M# is only supported in real mode.</p> <p>A20M# is an asynchronous signal. However, to ensure recognition of this signal following an Input/Output write instruction, it must be valid along with the TRDY# assertion of the corresponding Input/Output Write bus transaction.</p>												
ADS#	Input/ Output	<p>ADS# (Address Strobe) is asserted to indicate the validity of the transaction address on the A[35:3]# and REQ[4:0]# pins. All bus agents observe the ADS# activation to begin parity checking, protocol checking, address decode, internal snoop, or deferred reply ID match operations associated with the new transaction.</p>												
ADSTB[1:0]#	Input/ Output	<p>Address strobes are used to latch A[35:3]# and REQ[4:0]# on their rising and falling edges. Strobes are associated with signals as shown below.</p> <table><tr><th>Signals</th><th>Associated Strobe</th></tr><tr><td>REQ[4:0]#, A[16:3]#</td><td>ADSTB0#</td></tr><tr><td>A[35:17]#</td><td>ADSTB1#</td></tr></table>	Signals	Associated Strobe	REQ[4:0]#, A[16:3]#	ADSTB0#	A[35:17]#	ADSTB1#						
Signals	Associated Strobe													
REQ[4:0]#, A[16:3]#	ADSTB0#													
A[35:17]#	ADSTB1#													
AP[1:0]#	Input/ Output	<p>AP[1:0]# (Address Parity) are driven by the request initiator along with ADS#, A[35:3]#, and the transaction type on the REQ[4:0]#. A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. This allows parity to be high when all the covered signals are high. AP[1:0]# should connect the appropriate pins of all Pentium 4 processors with 512-KB L2 cache on 0.13 micron process system bus agents. The following table defines the coverage model of these signals.</p> <table><tr><th>Request Signals</th><th>subphase 1</th><th>subphase 2</th></tr><tr><td>A[35:24]#</td><td>AP0#</td><td>AP1#</td></tr><tr><td>A[23:3]#</td><td>AP1#</td><td>AP0#</td></tr><tr><td>REQ[4:0]#</td><td>AP1#</td><td>AP0#</td></tr></table>	Request Signals	subphase 1	subphase 2	A[35:24]#	AP0#	AP1#	A[23:3]#	AP1#	AP0#	REQ[4:0]#	AP1#	AP0#
Request Signals	subphase 1	subphase 2												
A[35:24]#	AP0#	AP1#												
A[23:3]#	AP1#	AP0#												
REQ[4:0]#	AP1#	AP0#												
BCLK[1:0]	Input	<p>The differential pair BCLK (Bus Clock) determines the system bus frequency. All processor system bus agents must receive these signals to drive their outputs and latch their inputs.</p> <p>All external timing parameters are specified with respect to the rising edge of BCLK0 crossing V_{CROSS}.</p>												

Table 21. Signal Description (Sheet 2 of 8)

Name	Type	Description
BINIT#	Input/ Output	<p>BINIT# (Bus Initialization) may be observed and driven by all processor system bus agents and if used, must connect the appropriate pins of all such agents. If the BINIT# driver is enabled during power-on configuration, BINIT# is asserted to signal any bus condition that prevents reliable future operation.</p> <p>If BINIT# observation is enabled during power-on configuration, and BINIT# is sampled asserted, symmetric agents reset their bus LOCK# activity and bus request arbitration state machines. The bus agents do not reset their IOQ and transaction tracking state machines upon observation of BINIT# activation. Once the BINIT# assertion has been observed, the bus agents will re-arbitrate for the system bus and attempt completion of their bus queue and IOQ entries.</p> <p>If BINIT# observation is disabled during power-on configuration, a central agent may handle an assertion of BINIT# as appropriate to the error handling architecture of the system.</p>
BNR#	Input/ Output	BNR# (Block Next Request) is used to assert a bus stall by any bus agent who is unable to accept new bus transactions. During a bus stall, the current bus owner cannot issue any new transactions.
BPM[5:0]#	Input/ Output	<p>BPM[5:0]# (Breakpoint Monitor) are breakpoint and performance monitor signals. They are outputs from the processor which indicate the status of breakpoints and programmable counters used for monitoring processor performance. BPM[5:0]# should connect the appropriate pins of all Pentium 4 processors with 512-KB L2 cache on 0.13 micron process system bus agents.</p> <p>BPM4# provides PRDY# (Probe Ready) functionality for the TAP port. PRDY# is a processor output used by debug tools to determine processor debug readiness.</p> <p>BPM5# provides PREQ# (Probe Request) functionality for the TAP port. PREQ# is used by debug tools to request debug operation of the processor.</p> <p>Please refer to the appropriate Platform Design Guide for more detailed information.</p> <p>These signals do not have on-die termination and must be terminated on the system board.</p>
BPRI#	Input	BPRI# (Bus Priority Request) is used to arbitrate for ownership of the processor system bus. It must connect the appropriate pins of all processor system bus agents. Observing BPRI# active (as asserted by the priority agent) causes all other agents to stop issuing new requests, unless such requests are part of an ongoing locked operation. The priority agent keeps BPRI# asserted until all of its requests are completed, then releases the bus by deasserting BPRI#.
BR0#	Input/ Output	<p>BR0# drives the BREQ0# signal in the system and is used by the processor to request the bus. During power-on configuration this pin is sampled to determine the agent ID = 0.</p> <p>This signal does not have on-die termination and must be terminated.</p>
BSEL[1:0]	Input/ Output	BSEL[1:0] (Bus Select) are used to select the processor input clock frequency. Table 5 defines the possible combinations of the signals and the frequency associated with each combination. The required frequency is determined by the processor, chipset and clock synthesizer. All agents must operate at the same frequency. For more information about these pins, including termination recommendations refer to Section 2.9 and the appropriate platform design guidelines.
COMP[1:0]	Analog	COMP[1:0] must be terminated on the system board using precision resistors. Refer to the appropriate Platform Design Guide for details on implementation.

Table 21. Signal Description (Sheet 3 of 8)

Name	Type	Description															
D[63:0]#	Input/ Output	<p>D[63:0]# (Data) are the data signals. These signals provide a 64-bit data path between the processor system bus agents, and must connect the appropriate pins on all such agents. The data driver asserts DRDY# to indicate a valid data transfer.</p> <p>D[63:0]# are quad-pumped signals and will thus be driven four times in a common clock period. D[63:0]# are latched off the falling edge of both DSTBP[3:0]# and DSTBN[3:0]#. Each group of 16 data signals correspond to a pair of one DSTBP# and one DSTBN#. The following table shows the grouping of data signals to data strobes and DBI#.</p> <p>Quad-Pumped Signal Groups</p> <table><tr><th>Data Group</th><th>DSTBN#/ DSTBP#</th><th>DBI#</th></tr><tr><td>D[15:0]#</td><td>0</td><td>0</td></tr><tr><td>D[31:16]#</td><td>1</td><td>1</td></tr><tr><td>D[47:32]#</td><td>2</td><td>2</td></tr><tr><td>D[63:48]#</td><td>3</td><td>3</td></tr></table> <p>Furthermore, the DBI# pins determine the polarity of the data signals. Each group of 16 data signals corresponds to one DBI# signal. When the DBI# signal is active, the corresponding data group is inverted and therefore sampled active high.</p>	Data Group	DSTBN#/ DSTBP#	DBI#	D[15:0]#	0	0	D[31:16]#	1	1	D[47:32]#	2	2	D[63:48]#	3	3
Data Group	DSTBN#/ DSTBP#	DBI#															
D[15:0]#	0	0															
D[31:16]#	1	1															
D[47:32]#	2	2															
D[63:48]#	3	3															
DBI[3:0]#	Input/ Output	<p>DBI[3:0]# (Data Bus Inversion) are source synchronous and indicate the polarity of the D[63:0]# signals. The DBI[3:0]# signals are activated when the data on the data bus is inverted. The bus agent will invert the data bus signals if more than half the bits, within the covered group, would change level in the next cycle.</p> <p>DBI[3:0]# Assignment To Data Bus</p> <table><tr><th>Bus Signal</th><th>Data Bus Signals</th></tr><tr><td>DBI3#</td><td>D[63:48]#</td></tr><tr><td>DBI2#</td><td>D[47:32]#</td></tr><tr><td>DBI1#</td><td>D[31:16]#</td></tr><tr><td>DBI0#</td><td>D[15:0]#</td></tr></table>	Bus Signal	Data Bus Signals	DBI3#	D[63:48]#	DBI2#	D[47:32]#	DBI1#	D[31:16]#	DBI0#	D[15:0]#					
Bus Signal	Data Bus Signals																
DBI3#	D[63:48]#																
DBI2#	D[47:32]#																
DBI1#	D[31:16]#																
DBI0#	D[15:0]#																
DBR#	Output	<p>DBR# (Data Bus Reset) is used only in processor systems where no debug port is implemented on the system board. DBR# is used by a debug port interposer so that an in-target probe can drive system reset. If a debug port is implemented in the system, DBR# is a no connect in the system. DBR# is not a processor signal.</p>															
DBSY#	Input/ Output	<p>DBSY# (Data Bus Busy) is asserted by the agent responsible for driving data on the processor system bus to indicate that the data bus is in use. The data bus is released after DBSY# is deasserted. This signal must connect the appropriate pins on all processor system bus agents.</p>															
DEFER#	Input	<p>DEFER# is asserted by an agent to indicate that a transaction cannot be guaranteed in-order completion. Assertion of DEFER# is normally the responsibility of the addressed memory or Input/Output agent. This signal must connect the appropriate pins of all processor system bus agents.</p>															
DP[3:0]#	Input/ Output	<p>DP[3:0]# (Data parity) provide parity protection for the D[63:0]# signals. They are driven by the agent responsible for driving D[63:0]#, and must connect the appropriate pins of all Pentium 4 processor with 512-KB L2 cache on 0.13 micron process system bus agents.</p>															

Table 21. Signal Description (Sheet 4 of 8)

Name	Type	Description										
DRDY#	Input/ Output	DRDY# (Data Ready) is asserted by the data driver on each data transfer, indicating valid data on the data bus. In a multi-common clock data transfer, DRDY# may be deasserted to insert idle clocks. This signal must connect the appropriate pins of all processor system bus agents.										
DSTBN[3:0]#	Input/ Output	<div>Data strobe used to latch in D[63:0]#.</div> <table><tr><th>Signals</th><th>Associated Strobe</th></tr><tr><td>D[15:0]#, DBI0#</td><td>DSTBN0#</td></tr><tr><td>D[31:16]#, DBI1#</td><td>DSTBN1#</td></tr><tr><td>D[47:32]#, DBI2#</td><td>DSTBN2#</td></tr><tr><td>D[63:48]#, DBI3#</td><td>DSTBN3#</td></tr></table>	Signals	Associated Strobe	D[15:0]#, DBI0#	DSTBN0#	D[31:16]#, DBI1#	DSTBN1#	D[47:32]#, DBI2#	DSTBN2#	D[63:48]#, DBI3#	DSTBN3#

D[47:32]#, DBI2#	DSTBP2#											
D[63:48]#, DBI3#	DSTBP3#											
FERR#/PBE#	Output	FERR#/PBE# (floating point error/pending break event) is a multiplexed signal which is qualified by STPCLK#. When STPCLK# is not asserted, FERR# indicates a floating-point error and will be asserted when the processor detects an unmasked floating-point error. When STPCLK# is not asserted, FERR#/PBE# is similar to the ERROR# signal on the Intel 387 coprocessor, and is included for compatibility with systems using Microsoft MS-DOS*-type floating-point error reporting. When STPCLK# is asserted, an assertion of FERR#/PBE# indicates that the processor has a pending break event waiting for service. The assertion of FERR#/PBE# indicates that the processor should be returned to the Normal state. When FERR#/PBE# is asserted, indicating a break event, it will remain asserted until STPCLK# is deasserted. For addition information on the pending break event functionality, including the identification of support of the feature and enable/disable information, refer to the <i>IA-32 Intel® Architecture Software Developer's Manual (Vol. 1 - Vol. 3)</i> and the <i>Intel® Processor Identification and the CPUID Instruction</i> application note.										
GTLREF	Input	GTLREF determines the signal reference level for AGTL+ input pins. GTLREF should be set at 2/3 V _{CC} . GTLREF is used by the AGTL+ receivers to determine if a signal is a logical 0 or logical 1. Refer to the appropriate Platform Design Guide for more information.										
HIT# HITM#	Input/ Output Input/ Output	HIT# (Snoop Hit) and HITM# (Hit Modified) convey transaction snoop operation results. Any system bus agent may assert both HIT# and HITM# together to indicate that it requires a snoop stall, which can be continued by reasserting HIT# and HITM# together.										
IERR#	Output	<div>IERR# (Internal Error) is asserted by a processor as the result of an internal error. Assertion of IERR# is usually accompanied by a SHUTDOWN transaction on the processor system bus. This transaction may optionally be converted to an external error signal (e.g., NMI) by system core logic. The processor will keep IERR# asserted until the assertion of RESET#.</div> <div>This signal does not have on-die termination and must be terminated on the system board.</div>										

Table 21. Signal Description (Sheet 5 of 8)

Name	Type	Description
IGNNE#	Input	IGNNE# (Ignore Numeric Error) is asserted to force the processor to ignore a numeric error and continue to execute noncontrol floating-point instructions. If IGNNE# is deasserted, the processor generates an exception on a noncontrol floating-point instruction if a previous floating-point instruction caused an error. IGNNE# has no effect when the NE bit in control register 0 (CR0) is set. IGNNE# is an asynchronous signal. However, to ensure recognition of this signal following an Input/Output write instruction, it must be valid along with the TRDY# assertion of the corresponding Input/Output Write bus transaction.
INIT#	Input	INIT# (Initialization), when asserted, resets integer registers inside the processor without affecting its internal caches or floating-point registers. The processor then begins execution at the power-on Reset vector configured during power-on configuration. The processor continues to handle snoop requests during INIT# assertion. INIT# is an asynchronous signal and must connect the appropriate pins of all processor system bus agents. If INIT# is sampled active on the active to inactive transition of RESET#, then the processor executes its Built-in Self-Test (BIST).
ITPCLKOUT[1:0]	Output	ITPCLKOUT[1:0] is an uncompensated differential clock output that is a delayed copy of BCLK[1:0], which is an input to the processor. This clock output can be used as the differential clock into the ITP port that is designed onto the motherboard. If ITPCLKOUT[1:0] outputs are not used, they must be terminated properly. Refer to Section 2.5 for additional details and termination requirements. Refer to the <i>ITP 700 Debug Port Design Guide</i> for details on implementing a debug port.
ITP_CLK[1:0]	Input	ITP_CLK[1:0] are copies of BCLK that are used only in processor systems where no debug port is implemented on the system board. ITP_CLK[1:0] are used as BCLK[1:0] references for a debug port implemented on an interposer. If a debug port is implemented in the system, ITP_CLK[1:0] are no connects in the system. These are not processor signals.
LINT[1:0]	Input	LINT[1:0] (Local APIC Interrupt) must connect the appropriate pins of all APIC Bus agents. When the APIC is disabled, the LINT0 signal becomes INTR, a maskable interrupt request signal, and LINT1 becomes NMI, a nonmaskable interrupt. INTR and NMI are backward compatible with the signals of those names on the Pentium processor. Both signals are asynchronous. Both of these signals must be software configured via BIOS programming of the APIC register space to be used either as NMI/INTR or LINT[1:0]. Because the APIC is enabled by default after Reset, operation of these pins as LINT[1:0] is the default configuration.
LOCK#	Input/Output	LOCK# indicates to the system that a transaction must occur atomically. This signal must connect the appropriate pins of all processor system bus agents. For a locked sequence of transactions, LOCK# is asserted from the beginning of the first transaction to the end of the last transaction. When the priority agent asserts BPRI# to arbitrate for ownership of the processor system bus, it will wait until it observes LOCK# deasserted. This enables symmetric agents to retain ownership of the processor system bus throughout the bus locked operation and ensure the atomicity of lock.

Table 21. Signal Description (Sheet 6 of 8)

Name	Type	Description
MCERR#	Input/ Output	<p>MCERR# (Machine Check Error) is asserted to indicate an unrecoverable error without a bus protocol violation. It may be driven by all processor system bus agents.</p> <p>MCERR# assertion conditions are configurable at a system level. Assertion options are defined by the following options:</p> <ul style="list-style-type: none"> Enabled or disabled. Asserted, if configured, for internal errors along with IERR#. Asserted, if configured, by the request initiator of a bus transaction after it observes an error. Asserted by any bus agent when it observes an error in a bus transaction. <p>For more details regarding machine check architecture, please refer to the <i>IA-32 Intel® Software Developer's Manual, Volume 3: System Programming Guide</i>.</p>
PROCHOT#	Output	<p>PROCHOT# (Processor Hot) will go active when the processor temperature monitoring sensor detects that the processor has reached its maximum safe operating temperature. This indicates that the processor Thermal Control Circuit has been activated, if enabled. See Section 6.3 for more details.</p>
PWRGOOD	Input	<p>PWRGOOD (Power Good) is a processor input. The processor requires this signal to be a clean indication that the clocks and power supplies are stable and within their specifications. 'Clean' implies that the signal will remain low (capable of sinking leakage current), without glitches, from the time that the power supplies are turned on until they come within specification. The signal must then transition monotonically to a high state.</p> <p>The PWRGOOD signal must be supplied to the processor; it is used to protect internal circuits against voltage sequencing issues. It should be driven high throughout boundary scan operation.</p>
REQ[4:0]#	Input/ Output	<p>REQ[4:0]# (Request Command) must connect the appropriate pins of all processor system bus agents. They are asserted by the current bus owner to define the currently active transaction type. These signals are source synchronous to ADSTB0#. Refer to the AP[1:0]# signal description for details on parity checking of these signals.</p>
RESET#	Input	<p>Asserting the RESET# signal resets the processor to a known state and invalidates its internal caches without writing back any of their contents. For a power-on Reset, RESET# must stay active for at least one millisecond after V_{CC} and BCLK have reached their proper specifications. On observing active RESET#, all system bus agents will deassert their outputs within two clocks. RESET# must not be kept asserted for more than 10 ms while PWRGOOD is asserted.</p> <p>A number of bus signals are sampled at the active-to-inactive transition of RESET# for power-on configuration. These configuration options are described in the Section 6.1.</p> <p>This signal does not have on-die termination and must be terminated on the system board.</p>
RS[2:0]#	Input	<p>RS[2:0]# (Response Status) are driven by the response agent (the agent responsible for completion of the current transaction), and must connect the appropriate pins of all processor system bus agents.</p>
RSP#	Input	<p>RSP# (Response Parity) is driven by the response agent (the agent responsible for completion of the current transaction) during assertion of RS[2:0]#, the signals for which RSP# provides parity protection. It must connect to the appropriate pins of all processor system bus agents.</p> <p>A correct parity signal is high if an even number of covered signals are low and low if an odd number of covered signals are low. While RS[2:0]# = 000, RSP# is also high, since this indicates it is not being driven by any agent guaranteeing correct parity.</p>

Table 21. Signal Description (Sheet 7 of 8)

Name	Type	Description
SKTOCC#	Output	SKTOCC# (Socket Occupied) will be pulled to ground by the processor. System board designers may use this pin to determine if the processor is present.
SLP#	Input	SLP# (Sleep), when asserted in Stop-Grant state, causes the processor to enter the Sleep state. During Sleep state, the processor stops providing internal clock signals to all units, leaving only the Phase-Locked Loop (PLL) still operating. Processors in this state will not recognize snoops or interrupts. The processor will only recognize the assertion of the RESET# signal, deassertion of SLP#, and removal of the BCLK input while in Sleep state. If SLP# is deasserted, the processor exits Sleep state and returns to Stop-Grant state, restarting its internal clock signals to the bus and processor core units. If the BCLK input is stopped while in the Sleep state the processor will exit the Sleep state and transition to the Deep Sleep state.
SMI#	Input	SMI# (System Management Interrupt) is asserted asynchronously by system logic. On accepting a System Management Interrupt, the processor saves the current state and enters System Management Mode (SMM). An SMI Acknowledge transaction is issued, and the processor begins program execution from the SMM handler. If SMI# is asserted during the deassertion of RESET# the processor will tristate its outputs.
STPCLK#	Input	Assertion of STPCLK# (Stop Clock) causes the processor to enter a low power Stop-Grant state. The processor issues a Stop-Grant Acknowledge transaction, and stops providing internal clock signals to all processor core units except the system bus and APIC units. The processor continues to snoop bus transactions and service interrupts while in Stop-Grant state. When STPCLK# is deasserted, the processor restarts its internal clock to all units and resumes execution. The assertion of STPCLK# has no effect on the bus clock; STPCLK# is an asynchronous input.
TCK	Input	TCK (Test Clock) provides the clock input for the processor Test Bus (also known as the Test Access Port).
TDI	Input	TDI (Test Data In) transfers serial test data into the processor. TDI provides the serial input needed for JTAG specification support.
TDO	Output	TDO (Test Data Out) transfers serial test data out of the processor. TDO provides the serial output needed for JTAG specification support.
TESTHI[12:8] TESTHI[5:0]	Input	TESTHI[12:8] and TESTHI[5:0] must be connected to a V _{CC} power source through a resistor for proper processor operation. See Section 2.5 for more details.
THERMDA	Other	Thermal Diode Anode. See Section 6.3.1 .
THERMDC	Other	Thermal Diode Cathode. See Section 6.3.1 .
THERMTRIP#	Output	Assertion of THERMTRIP# (Thermal Trip) indicates the processor junction temperature has reached a level where permanent silicon damage may occur. Measurement of the temperature is accomplished through an internal thermal sensor which is configured to trip at approximately 135°C. Upon assertion of THERMTRIP#, the processor will shut off its internal clocks (thus halting program execution) in an attempt to reduce the processor junction temperature. To protect the processor, its core voltage (V _{CC}) must be removed within 0.5 seconds of the assertion of THERMTRIP#. Once activated, THERMTRIP# remains latched until RESET# is asserted. While the assertion of the RESET# signal will de-assert THERMTRIP#, if the processor's junction temperature remains at or above the trip level, THERMTRIP# will again be asserted.
TMS	Input	TMS (Test Mode Select) is a JTAG specification support signal used by debug tools.
TRDY#	Input	TRDY# (Target Ready) is asserted by the target to indicate that it is ready to receive a write or implicit writeback data transfer. TRDY# must connect the appropriate pins of all system bus agents.

Table 21. Signal Description (Sheet 8 of 8)

Name	Type	Description
TRST#	Input	TRST# (Test Reset) resets the Test Access Port (TAP) logic. TRST# must be driven low during power on Reset. This can be done with a 680 Ω pull-down resistor.
V _{CCA}	Input	V _{CCA} provides isolated power for the internal processor core PLL's. Refer to the appropriate Platform Design Guide for complete implementation details.
V _{CCIOPLL}	Input	V _{CCIOPLL} provides isolated power for internal processor system bus PLL's. Follow the guidelines for V _{CCA} , and refer to the appropriate Platform Design Guide for complete implementation details.
V _{CCSENSE}	Output	V _{CCSENSE} is an isolated low impedance connection to processor core power (V _{CC}). It can be used to sense or measure power near the silicon with little noise.
VCCVID	Input	Independent 1.2V supply must be routed to VCCVID pin for the Pentium 4 processor with 5120-KB L2 cache on 0.13 micron process's Voltage Identification circuit.
VID[4:0]	Output	VID[4:0] (Voltage ID) pins are used to support automatic selection of power supply voltages (V _{cc}). Unlike previous generations of processors, these are open drain signals that are driven by the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process and must be pulled up to 3.3 V (max.) with 1 k Ω resistors. The voltage supply for these pins must be valid before the VR can supply V _{CC} to the processor. Conversely, the VR output must be disabled until the voltage supply for the VID pins becomes valid. The VID pins are needed to support the processor voltage specification variations. See Table 3 for definitions of these pins. The VR must supply the voltage that is requested by the pins, or disable itself.
V _{SSA}	Input	V _{SSA} is the isolated ground for internal PLLs.
V _{SSSENSE}	Output	V _{SSSENSE} is an isolated low impedance connection to processor core V _{SS} . It can be used to sense or measure ground near the silicon with little noise.

5.0 Thermal Specifications and Design Considerations

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process use an integrated heat spreader (IHS) for heatsink attachment which is intended to provide for multiple types of thermal solutions. This section will provide data necessary for development of a thermal solution. See [Figure 14](#) for an enlarged view of an example of the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process thermal solution. This is for illustration purposes only. For further thermal solution design details, please refer to the *Intel® Pentium® 4 Processor in the 478-Pin Package Thermal Design Guidelines*.

Note: The processor is either shipped by itself or with a heatsink for boxed processors. See [Chapter 7.0](#) for details on boxed processors.

Figure 14. Example Thermal Solution (Not to scale)

5.1 Thermal Specifications

Table 22 specifies the thermal design power dissipation envelope for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process. The Thermal Monitor feature (refer to Section 6.3) is designed to help protect the processor from overheating. For more details on the usage of this feature, refer to Section 6.3. To ensure maximum flexibility, systems should be designed to the Flexible Motherboard guidelines, even if a processor with a lower thermal dissipation is planned. **In all cases the Thermal Monitor feature must be enabled for the processor to be operating within the published specification.** Table 22 also lists the maximum and minimum processor temperature specifications for T_{CASE} . A thermal solution must be designed to ensure the temperature of the processor does not exceed these specifications.

Table 22. Processor Thermal Design Power

Processor and Core Frequency	Thermal Design Power ² (W)	Minimum T_{CASE} (°C)	Maximum T_{CASE} (°C)	Notes
2 GHz	52.4	5	68	
2.20 GHz	55.1	5	69	
2.26 GHz	56.0	5	70	
2.40 GHz	57.8	5	70	
2.53 GHz	59.3	5	71	

NOTES:

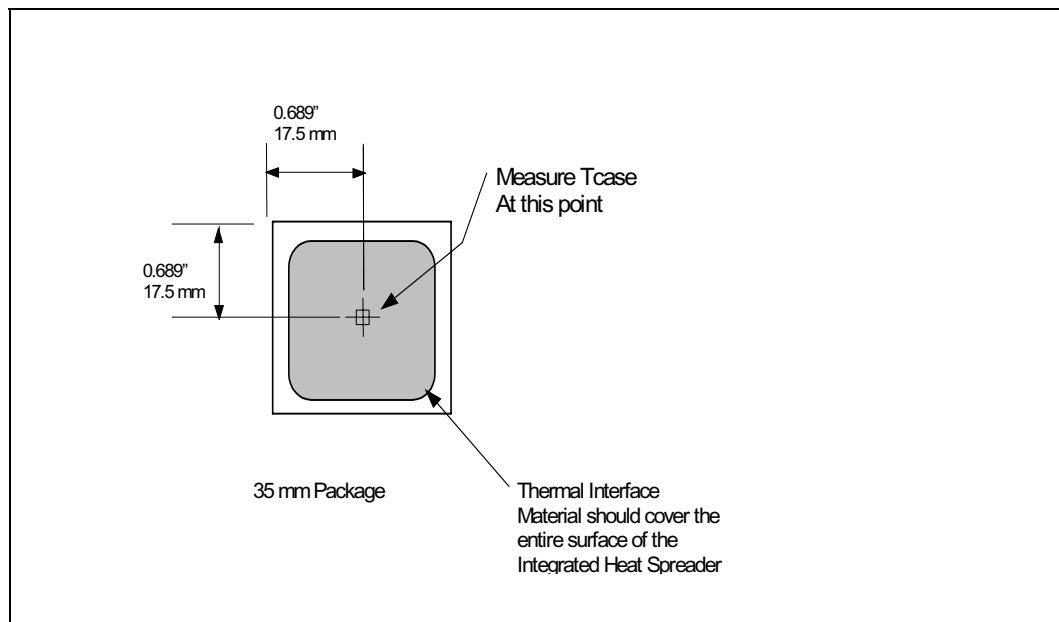

1. These values are specified at V_{CC_MAX} for the processor. Systems must be designed to ensure that the processor is not subjected to any static V_{CC} and I_{CC} combination wherein V_{CC} exceeds V_{CC_MAX} at specified I_{CC} . Please refer to loadline specifications in Chapter 2.
2. The numbers in this column reflect Intel's recommended design point and are not indicative of the maximum power the processor can dissipate under worst case conditions. For more details refer to the *Intel® Pentium® 4 Processor in the 478-Pin Package Thermal Design Guidelines*.

5.1.1 Measurements For Thermal Specifications

5.1.1.1 Processor Case Temperature Measurement

The maximum and minimum case temperature (T_{CASE}) for the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process is specified in Table 22. This temperature specification is meant to ensure correct and reliable operation of the processor. Figure 15 illustrates where Intel recommends T_{CASE} thermal measurements should be made.

Figure 15. Guideline Locations for Case Temperature (T_{CASE}) Thermocouple Placement

6.0 Features

6.1 Power-On Configuration Options

Several configuration options can be configured by hardware. The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process samples their hardware configuration at reset, on the active-to-inactive transition of RESET#. For specifications on these options, please refer to [Table 23](#).

The sampled information configures the processor for subsequent operation. These configuration options cannot be changed except by another reset. All resets reconfigure the processor; for reset purposes, the processor does not distinguish between a "warm" reset and a "power-on" reset.

Table 23. Power-On Configuration Option Pins

Configuration Option	Pin ¹
Output tristate	SMI#
Execute BIST	INIT#
In Order Queue pipelining (set IOQ depth to 1)	A7#
Disable MCERR# observation	A9#
Disable BINIT# observation	A10#
APIC Cluster ID (0-3)	A[12:11]#
Disable bus parking	A15#
Symmetric agent arbitration ID	BR0#

NOTE:

1. Asserting this signal during RESET# will select the corresponding option.

6.2 Clock Control and Low Power States

The use of AutoHALT, Stop-Grant, Sleep, and Deep Sleep states is allowed in Pentium 4 processor with 512-KB L2 cache on 0.13 micron process-based systems to reduce power consumption by stopping the clock to internal sections of the processor, depending on each particular state. See [Figure 16](#) for a visual representation of the processor low power states.

6.2.1 Normal State—State 1

This is the normal operating state for the processor.

6.2.2 AutoHALT Powerdown State—State 2

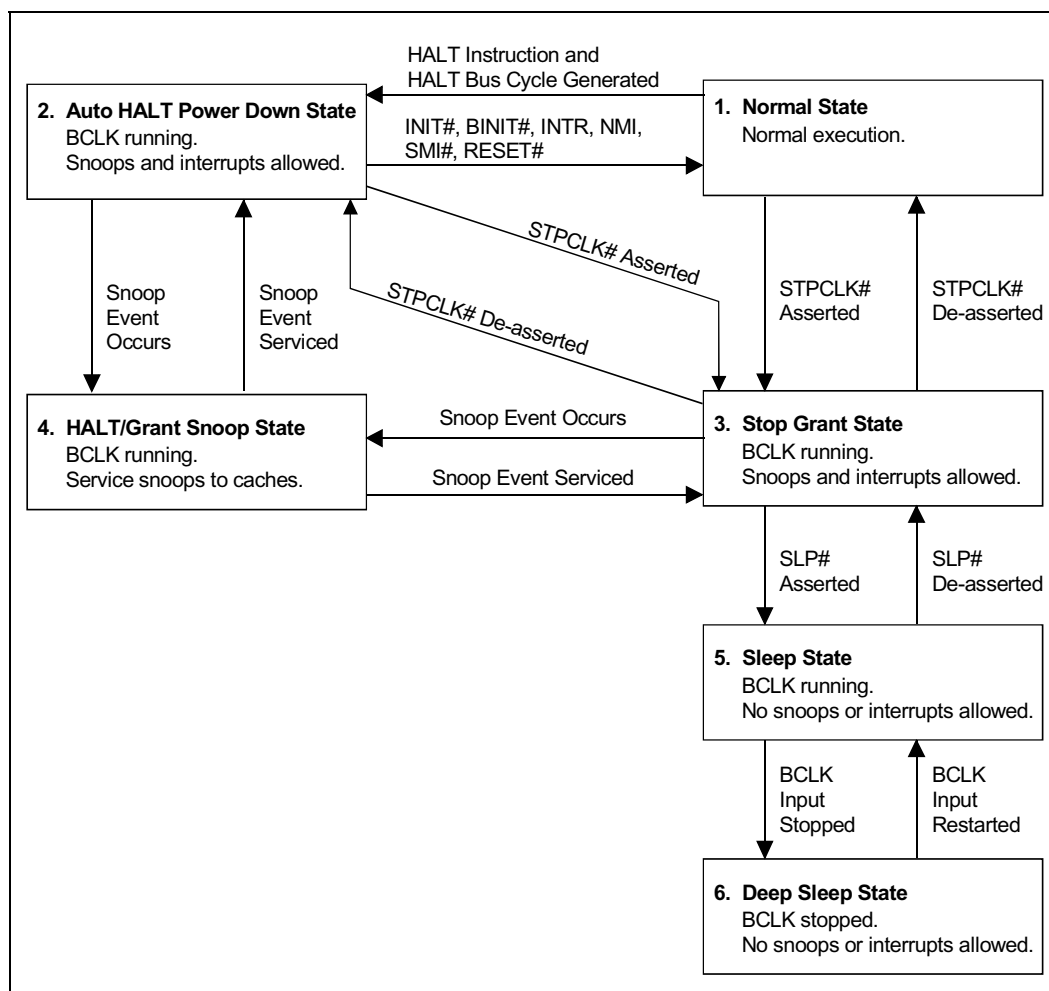

AutoHALT is a low power state entered when the processor executes the HALT instruction. The processor will transition to the Normal state upon the occurrence of SMI#, BINIT#, INIT#, or LINT[1:0] (NMI, INTR). RESET# will cause the processor to immediately initialize itself.

The return from a System Management Interrupt (SMI) handler can be to either Normal Mode or the AutoHALT Power Down state. See the *Intel® Architecture Software Developer's Manual, Volume III: System Programmer's Guide* for more information.

The system can generate a STPCLK# while the processor is in the AutoHALT Power Down state. When the system deasserts the STPCLK# interrupt, the processor will return execution to the HALT state.

While in AutoHALT Power Down state, the processor will process bus snoops.

Figure 16. Stop Clock State Machine

6.2.3 Stop-Grant State—State 3

When the STPCLK# pin is asserted, the Stop-Grant state of the processor is entered 20 bus clocks after the response phase of the processor-issued Stop Grant Acknowledge special bus cycle.

Since the AGTL+ signal pins receive power from the system bus, these pins should not be driven (allowing the level to return to V_{CC}) for minimum power drawn by the termination resistors in this state. In addition, all other input pins on the system bus should be driven to the inactive state.

BINIT# will not be serviced while the processor is in Stop-Grant state. The event will be latched and can be serviced by software upon exit from the Stop Grant state.

RESET# will cause the processor to immediately initialize itself, but the processor will stay in Stop-Grant state. A transition back to the Normal state will occur with the de-assertion of the STPCLK# signal. When re-entering the Stop Grant state from the Sleep state, STPCLK# should only be de-asserted one or more bus clocks after the de-assertion of SLP#.

A transition to the HALT/Grant Snoop state will occur when the processor detects a snoop on the system bus (see [Section 6.2.4](#)). A transition to the Sleep state (see [Section 6.2.5](#)) will occur with the assertion of the SLP# signal.

While in the Stop-Grant State, SMI#, INIT#, BINIT# and LINT[1:0] will be latched by the processor, and only serviced when the processor returns to the Normal State. Only one occurrence of each event will be recognized upon return to the Normal state.

While in Stop-Grant state, the processor will process a system bus snoop.

6.2.4 HALT/Grant Snoop State—State 4

The processor will respond to snoop transactions on the system bus while in Stop-Grant state or in AutoHALT Power Down state. During a snoop transaction, the processor enters the HALT/Grant Snoop state. The processor will stay in this state until the snoop on the system bus has been serviced (whether by the processor or another agent on the system bus). After the snoop is serviced, the processor will return to the Stop-Grant state or AutoHALT Power Down state, as appropriate.

6.2.5 Sleep State—State 5

The Sleep state is a very low power state in which the processor maintains its context, maintains the phase-locked loop (PLL), and has stopped all internal clocks. The Sleep state can only be entered from Stop-Grant state. Once in the Stop-Grant state, the processor will enter the Sleep state upon the assertion of the SLP# signal. The SLP# pin should only be asserted when the processor is in the Stop Grant state. SLP# assertions while the processor is not in the Stop Grant state is out of specification and may result in unapproved operation.

Snoop events that occur while in Sleep State or during a transition into or out of Sleep state will cause unpredictable behavior.

In the Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals (with the exception of SLP# or RESET#) are allowed on the system bus while the processor is in Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behaviour.

If RESET# is driven active while the processor is in the Sleep state, and held active as specified in the RESET# pin specification, then the processor will reset itself, ignoring the transition through Stop-Grant State. If RESET# is driven active while the processor is in the Sleep State, the SLP# and STPCLK# signals should be deasserted immediately after RESET# is asserted to ensure the processor correctly executes the Reset sequence.

While in the Sleep state, the processor is capable of entering its lowest power state, the Deep Sleep state, by stopping the BCLK[1:0] inputs. (See [Section 6.2.6](#)). Once in the Sleep or Deep Sleep states, the SLP# pin must be de-asserted if another asynchronous system bus event needs to occur. The SLP# pin has a minimum assertion of one BCLK period.

When the processor is in Sleep state, it will not respond to interrupts or snoop transactions.

6.2.6 Deep Sleep State—State 6

Deep Sleep state is the lowest power state the processor can enter while maintaining context. Deep Sleep state is entered by stopping the BCLK[1:0] inputs (after the Sleep state was entered from the assertion of the SLP# pin). The processor is in Deep Sleep state immediately after BCLK[1:0] is stopped. The BCLK[1:0] inputs should be stopped such that one is below V_{OL} and the other is above V_{OH} . Stopping the BCLK input lowers the overall current consumption to leakage levels.

To re-enter the Sleep state, the BCLK input must be restarted. A period of 1 ms (to allow for PLL stabilization) must occur before the processor can be considered to be in the Sleep State. Once in the Sleep state, the SLP# pin can be deasserted to re-enter the Stop-Grant state.

While in Deep Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals are allowed on the system bus while the processor is in Deep Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior. The processor has to stay in Deep Sleep mode for a minimum of 25 μ s.

6.3 Thermal Monitor

The Thermal Monitor feature found in the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process allows system designers to design lower cost thermal solutions without compromising system integrity or reliability. By using a factory-tuned, precision on-die thermal sensor, and a fast acting thermal control circuit (TCC), the processor, without the aid of any additional software or hardware, can keep the processor's die temperature within factory specifications under nearly all conditions. Thermal Monitor thus allows the processor and system thermal solutions to be designed much closer to the power envelopes of real applications, instead of being designed to the much higher processor maximum power envelopes.

Thermal Monitor controls the processor temperature by modulating (starting and stopping) the processor core clocks. The processor clocks are modulated when the TCC is activated. Thermal Monitor uses two modes to activate the TCC: Automatic mode and On-Demand mode. **Automatic mode is required for the processor to operate within specifications and must first be enabled via BIOS.** Once automatic mode is enabled,

the TCC will activate only when the internal die temperature is at very near the temperature limits of the processor. When the TCC is enabled, and a high temperature situation exists (i.e. TCC is active), the clocks will be modulated by alternately turning the clocks off and on at a duty cycle specific to the processor (typically 30-50%). Cycle times are processor speed dependent and will decrease linearly as processor core frequencies increase. Once the temperature has returned to a non-critical level, modulation ceases and TCC goes inactive. A small amount of hysteresis has been included to prevent rapid active/inactive transitions of the TCC when the processor temperature is near the trip point. Processor performance will be decreased by approximately the same amount as the duty cycle when the TCC is active, however, with a properly designed and characterized thermal solution, the TCC will only be activated briefly when running the most power intensive applications in a high ambient temperature environment.

For automatic mode, the duty cycle is factory configured and cannot be modified. Also, automatic mode does not require any additional hardware, software drivers or interrupt handling routines.

The TCC may also be activated via On-Demand mode. If bit 4 of the ACPI Thermal Monitor Control Register is written to a "1" the TCC will be activated immediately, independent of the processor temperature. When using On-Demand mode to activate the TCC, the duty cycle of the clock modulation is programmable via bits 3:1 of the same ACPI Thermal Monitor Control Register. In automatic mode, the duty cycle is fixed, however in On-Demand mode, the duty cycle can be programmed from 12.5% on/ 87.5% off, to 87.5% on/12.5% off in 12.5% increments. On-Demand mode may be used at the same time Automatic mode is enabled, however, if the system tries to enable the TCC via On-Demand mode at the same time automatic mode is enabled AND a high temperature condition exists, the duty cycle of the automatic mode will override the duty cycle selected by the On-Demand mode.

An external signal, PROCHOT# (processor hot) is asserted when the processor detects that its temperature is at the thermal trip point. Bus snooping and interrupt latching are also active while the TCC is active. The temperature at which the thermal control circuit activates is not user configurable and is not software visible.

Besides the thermal sensor and TCC, the Thermal Monitor feature also includes one ACPI register, performance monitoring logic, bits in three model specific registers (MSR), and one I/O pin (PROCHOT#). All are available to monitor and control the state of the Thermal Monitor feature. Thermal Monitor can be configured to generate an interrupt upon the assertion or de-assertion of PROCHOT#.

If automatic mode is disabled the processor will be operating out of specification. Regardless of enabling of the automatic or On-Demand modes, in the event of a catastrophic cooling failure, the processor will automatically shut down when the silicon has reached a temperature of approximately 135 °C. At this point the system bus signal THERMTRIP# will go active and stay active until RESET# has been initiated. THERMTRIP# activation is independent of processor activity and does not generate any bus cycles. If THERMTRIP# is asserted, processor core voltage (V_{CC}) must be removed within 0.5 seconds.

6.3.1 Thermal Diode

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process incorporates an on-die thermal diode. A thermal sensor located on the system board may monitor the die temperature of the processor for thermal management/long term die temperature change purposes. Table 24 and Table 25 provide the diode parameter and interface specifications. This thermal diode is separate from the Thermal Monitor's thermal sensor and cannot be used to predict the behavior of the Thermal Monitor.

Table 24. Thermal Diode Parameters

Symbol	Parameter	Min	Typ	Max	Unit	Notes ¹
I_{FW}	Forward Bias Current	5		300	μA	1
n	Diode Ideality Factor	1.0011	1.0021	1.0030		2,3,4
R_T	Series Resistance		3.64			2,3,4

NOTES:

- Intel does not support or recommend operation of the thermal diode under reverse bias.
- Characterized at 75C.
- Not 100% tested. Specified by design characterization.
- The ideality factor, n , represents the deviation from ideal diode behavior as exemplified by the diode equation:

$$I_{FW} = I_s * (e^{(qV_D/nkT)} - 1)$$
 Where I_s = saturation current, q = electronic charge, V_D = voltage across the diode, k = Boltzmann Constant, and T = absolute temperature (Kelvin).
- The series resistance, R_T , is provided to allow for a more accurate measurement of the diode junction temperature. R_T as defined includes the pins of the processor but does not include any socket resistance or board trace resistance between the socket and the external remote diode thermal sensor. R_T can be used by remote diode thermal sensors with automatic series resistance cancellation to calibrate out this error term. Another application is that a temperature offset can be manually calculated and programmed into an offset register in the remote diode thermal sensors as exemplified by the equation:

$$T_{error} = [R_T * (N-1) * I_{FWmin}] / [(nk/q) * \ln N]$$
 Where T_{error} = sensor temperature error, N = sensor current ration, k = Boltzmann Constant, q = electronic charge.

Table 25. Thermal Diode Interface

THERMDC	C4	diode cathode

7.0 Boxed Processor Specifications

7.1 Introduction

The Pentium 4 processor with 512-KB L2 cache on 0.13 micron process will also be offered as an Intel® boxed processor. Intel boxed processors are intended for system integrators who build systems from motherboards and standard components. The boxed Pentium 4 processor with 512-KB L2 cache on 0.13 micron process will be supplied with a cooling solution. This chapter documents motherboard and system requirements for the cooling solution that will be supplied with the boxed Pentium 4 processor with 512-KB L2 cache on 0.13 micron process. This chapter is particularly important for OEMs that manufacture motherboards for system integrators. Unless otherwise noted, all figures in this chapter are dimensioned in millimeters and inches [in brackets]. [Figure 17](#) shows a mechanical representation of a boxed Pentium 4 processor with 512-KB L2 cache on 0.13 micron process.

Note: Drawings in this section reflect only the specifications on the Intel boxed processor product. These dimensions should not be used as a generic keep-out zone for all cooling solutions. It is the system designer's responsibility to consider their proprietary cooling solution when designing to the required keep-out zone on their system platform and chassis. Refer to the *Intel® Pentium® 4 Processor with 512KB L2 cache on .13 micron process Thermal Design Guidelines* for further guidance. Contact your local Intel Sales Representative for this document.

Figure 17. Mechanical Representation of the Boxed Processor

NOTE: The airflow is into the center and out of the sides of the fan heatsink.

7.2 Mechanical Specifications

7.2.1 Boxed Processor Cooling Solution Dimensions

This section documents the mechanical specifications of the boxed Pentium 4 processor with 512-KB L2 cache on 0.13 micron process. The boxed processor will be shipped with an unattached fan heatsink. [Figure 17](#) shows a mechanical representation of the boxed Pentium 4 processor with 512-KB L2 cache on 0.13 micron process.

Clearance is required around the fan heatsink to ensure unimpeded airflow for proper cooling. The physical space requirements and dimensions for the boxed processor with assembled fan heatsink are shown in [Figure 18](#) (Side Views), and [Figure 19](#) (Top View). The airspace requirements for the boxed processor fan heatsink must also be incorporated into new motherboard and system designs. Airspace requirements are shown in [Figure 22](#) and [Figure 23](#). Note that some figures have centerlines shown (marked with alphabetic designations) to clarify relative dimensioning.

Figure 18. Side View Space Requirements for the Boxed Processor

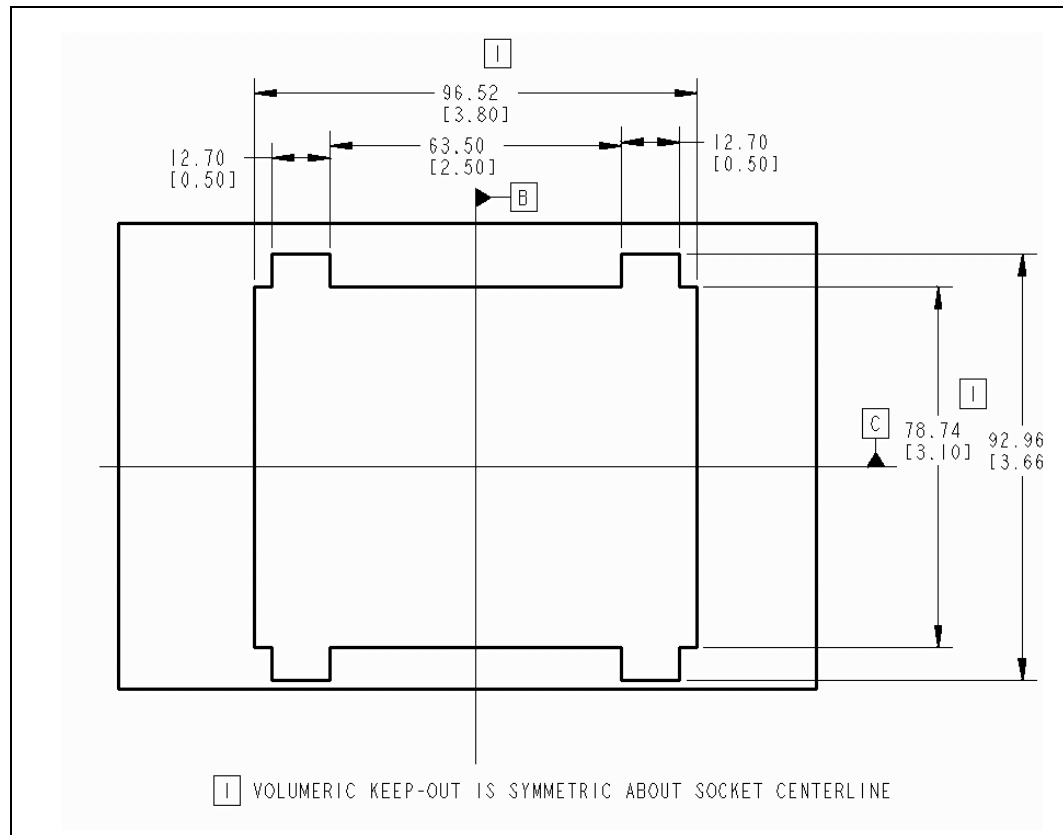

Figure 19. Top View Space Requirements for the Boxed Processor

7.2.2 Boxed Processor Fan Heatsink Weight

The boxed processor fan heatsink will not weigh more than 450 grams. See [Chapter 5.0](#) and the *Intel® Pentium® 4 Processor with 512KB L2 cache on .13 micron process Thermal Design Guidelines* for details on the processor weight and heatsink requirements.

7.2.3 Boxed Processor Retention Mechanism and Heatsink Assembly

The boxed processor thermal solution requires a processor retention mechanism and a heatsink attach clip assembly, to secure the processor and fan heatsink in the baseboard socket. The boxed processor will not ship with retention mechanisms but will ship with the heatsink attach clip assembly. Motherboards designed for use by system integrators should include the retention mechanism that supports the boxed Pentium 4 processor with 512-KB L2 cache on 0.13 micron process. Motherboard documentation should include appropriate retention mechanism installation instructions.

Note: The processor retention mechanism based on the Intel reference design should be used, to ensure compatibility with the heatsink attach clip assembly and the boxed processor thermal solution. The heatsink attach clip assembly is latched to the retention tab features at each corner of the retention mechanism.

The target load applied by the clips to the processor heat spreader for Intel's reference design is 75 ± 15 lbf (maximum load is constrained by the package load capability). It is normal to observe a bow or bend in the board due to this compressive load on the processor package and the socket. The level of bow or bend depends on the motherboard material properties and component layout. Any additional board stiffening devices such as plates are not necessary and should not be used along with the reference mechanical components and boxed processor. Using such devices increase the compressive load on the processor package and socket, likely beyond the maximum load that is specified for those components. Refer to the *Intel® Pentium® 4 Processor with 512KB L2 cache on .13 micron process Thermal Design Guidelines* for details on the Intel reference design.

7.3 Electrical Requirements

7.3.1 Fan Heatsink Power Supply

The boxed processor's fan heatsink requires a +12 V power supply. A fan power cable will be shipped with the boxed processor to draw power from a power header on the motherboard. The power cable connector and pinout are shown in [Figure 20](#). Motherboards must provide a matched power header to support the boxed processor. [Table 26](#) contains specifications for the input and output signals at the fan heatsink connector. The fan heatsink outputs a SENSE signal, which is an open-collector output that pulses at a rate of two pulses per fan revolution. A motherboard pull-up resistor provides V_{OH} to match the system board-mounted fan speed monitor requirements, if applicable. Use of the SENSE signal is optional. If the SENSE signal is not used, pin 3 of the connector should be tied to GND.

Note: The motherboard must supply a constant +12V to the processor's power header to ensure proper operation of the variable speed fan for the boxed processor.

The power header on the baseboard must be positioned to allow the fan heatsink power cable to reach it. The power header identification and location should be documented in the platform documentation, or on the system board itself. [Figure 21](#) shows the location of the fan power connector relative to the processor socket. The motherboard power header should be positioned within 4.33 inches from the center of the processor socket.

Figure 20. Boxed Processor Fan Heatsink Power Cable Connector Description

Table 26. Fan Heatsink Power and Signal Specifications

Description	Min	Typ	Max	Unit	Notes
+12 V: 12 Volt fan power supply	10.2	12	13.8	V	
IC: Fan current draw			740	mA	
SENSE: SENSE frequency		2		pulses per fan revolution	1

NOTE:
1. Motherboard should pull this pin up to V_{CC} with a resistor.

Figure 21. MotherBoard Power Header Placement Relative to Processor Socket

7.4 Thermal Specifications

This section describes the cooling requirements of the fan heatsink solution utilized by the boxed processor.

7.4.1 Boxed Processor Cooling Requirements

The boxed processor may be directly cooled with a fan heatsink. However, meeting the processor's temperature specification is also a function of the thermal design of the entire system, and ultimately the responsibility of the system integrator. The processor temperature specification is found in [Chapter 5.0](#) of this document. The boxed processor fan heatsink is able to keep the processor temperature within the specifications (see [Table 22](#)) in chassis that provide good thermal management. For the boxed processor fan heatsink to operate properly, it is critical that the airflow provided to the fan heatsink is unimpeded. Airflow is into the center and out of the sides of the fan heatsink. Airspace is required around the fan to ensure that the airflow through the fan heatsink is not blocked. Blocking the airflow to the fan heatsink reduces the cooling efficiency and decreases fan life. [Figure 22](#) and [Figure 23](#) illustrate an acceptable airspace clearance for the fan heatsink. The air temperature entering the fan should be kept below 40 °C. Again, meeting the processor's temperature specification is the responsibility of the system integrator.

Figure 22. Boxed Processor Fan Heatsink Airspace Keep-Out Requirements (side 1 view)

Figure 23. Boxed Processor Fan Heatsink Airspace Keep-Out Requirements (side 2 view)

7.4.2 Variable Speed Fan

The boxed processor fan will operate at different speeds over a short range of internal chassis temperatures. This allows the processor fan to operate at a lower speed and noise level, while internal chassis temperatures are low. If internal chassis temperature increases beyond a lower set point, the fan speed will rise linearly with the internal temperature until the higher set point is reached. At that point, the fan speed is at its maximum. As fan speed increases, so does fan noise levels. Systems should be designed to provide adequate air around the boxed processor fan heatsink that remains below the lower set point. These set points, represented in [Figure 24](#) and [Table 27](#), can vary by a few degrees from fan heatsink to fan heatsink. The internal chassis temperature should be kept below 38 °C. Meeting the processor's temperature specification (see [Chapter 5.0](#)) is the responsibility of the system integrator.

Figure 24. Boxed Processor Fan Heatsink Set Points

Table 27. Boxed Processor Fan Heatsink Set Points

Boxed Processor Fan Heatsink Set Point (°C)	Boxed Processor Fan Speed	Notes
33	When the internal chassis temperature is below or equal to this set point, the fan operates at its lowest speed. Recommended maximum internal chassis temperature for nominal operating environment.	1
40	When the internal chassis temperature is at this point, the fan operates between its lowest and highest speeds. Recommended maximum internal chassis temperature for worst-case operating environment.	
43	When the internal chassis temperature is above or equal to this set point, the fan operates at its highest speed.	1

NOTE:

1. Set point variance is approximately ± 1 °C from fan heatsink to fan heatsink.

8.0 Debug Tools Specifications

Please refer to the *ITP 700 Debug Port Design Guide* and the appropriate platform design guidelines for more detailed information regarding debug tools specifications, such as integration details.

8.1 Logic Analyzer Interface (LAI)

Intel is working with two logic analyzer vendors to provide logic analyzer interfaces (LAIs) for use in debugging Pentium 4 processors with 512-KB L2 cache on 0.13 micron process systems. Tektronix and Agilent should be contacted to get specific information about their logic analyzer interfaces. The following information is general in nature. Specific information must be obtained from the logic analyzer vendor.

Due to the complexity of the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process systems, the LAI is critical in providing the ability to probe and capture system bus signals. There are two sets of considerations to keep in mind when designing a Pentium 4 processor with 512-KB L2 cache on 0.13 micron process system that can make use of an LAI: mechanical and electrical.

8.1.1 Mechanical Considerations

The LAI is installed between the processor socket and the processor. The LAI pins plug into the socket, while the processor pins plug into a socket on the LAI. Cabling that is part of the LAI egresses the system to allow an electrical connection between the processor and a logic analyzer. The maximum volume occupied by the LAI, known as the keepout volume, as well as the cable egress restrictions, should be obtained from the logic analyzer vendor. System designers must make sure that the keepout volume remains unobstructed inside the system. Note that it is possible that the keepout volume reserved for the LAI may differ from the space normally occupied by the Pentium 4 processor with 512-KB L2 cache on 0.13 micron process heatsink. If this is the case, the logic analyzer vendor will provide a cooling solution as part of the LAI.

8.1.2 Electrical Considerations

The LAI will also affect the electrical performance of the system bus; therefore, it is critical to obtain electrical load models from each of the logic analyzer vendors to be able to run system level simulations to prove that their tool will work in the system. Contact the logic analyzer vendor for electrical specifications and load models for the LAI solution they provide.
