CSE 3318-003 Lab Assignment 1

Due February 17

Goal:

Implementation of mergesort using linked list ideas for tables.

Requirements:

- 1. Write a program to read an input sequence and then produce an <u>array of links</u> giving the values in ascending order. The first line of the input file is the length of the sequence (n) and each of the remaining n lines is a non-negative integer. The first line of the output indicates the subscript of the smallest input value. Each of the remaining output lines is a triple consisting of a subscript along with the corresponding input sequence and link values.
- 2. Submit your C program on Canvas by 12:45 p.m. on February 17. One of the comment lines should include the compilation command used on OMEGA (5 point penalty for omitting this).

Getting Started:

- 1. Your program should read the input files by using Unix shell redirection (e.g. a.out<lab1.dat) to read the input from stdin (C). By using redirection, it is unnecessary to explicitly open and close the input file, nor should your program prompt for a file name. You should dynamically allocate tables for storing the input keys and the table of links. Unlike the mergesort in Notes 1 and CLRS, the table of keys is *never* modified.
- 2. The link values are <u>not</u> initialized before the recursive mergesort begins. Each link will be initialized to -1 when its sequence value is placed in a single-element list (at the bottom of the recursion's "tree").
- 3. The input sequence array and the link array may be global. Under this assumption, the following prototype may be used:

```
int mergeSort(int start,int count)
```

where start is the first subscript for a subarray of count elements. The returned int is the subscript of the first element in the resulting sorted sublist. The last element in the sublist will have a link value of -1.

- 4. The critical part of the code is a linear-time merge of two subarrays that previously had their link values set for ordered sublists. (Be sure to understand the merging concept from pp. 3-4 of Notes 1 before proceeding.) The merge will revise the link values to give a single ordered list.
- 5. If an input value appears more than once, those elements should be ordered by subscripts in the final list, i.e. your sort code will be stable.
- 6. Consider the following input file:

 The output (as subscript/value/link triples) will be:

8	3	irst element is at su	bscript 6
ŗ	5	5 1	
ŗ	5	5 –1	
2	2	2 4	
4	1	4 0	
:	3	3 3	
		1 7	
(0 5	
-		1 2	

Notice that the input sequence ordering has not changed.

7. Your code should NEVER scan a subarray to find the minimum key.
