*Online Computation And
Competitive Analysis
Borodin & El-Yaniv*

Statement of Exercise

Prove that CLOCK is
NOT a marking algorithm.

Notion of the k -phase

Recall any k -phase partition of σ contains k first requests for pages:

- j first requests for pages ***NOT in fast memory*** at start of phase.
- $k-j$ first requests for pages ***IN fast memory*** at start of phase.
- Any number of 2nd and greater requests for pages in fast memory as phase progresses.

Marking Algorithm Guarantee

Recall also the definition of a marking algorithm:

During any k -phase, any second or greater request for a page is serviced (without fault) from fast memory.

(Restate: Prior to end of phase, no page, once referenced is ever evicted in servicing a faulting request for some other page.)

Algorithm CLOCK

Text lists actions, but what is philosophy:

- Tour cache only to service faults.
- Always tour in fixed sequence.
- After initial fetch, if page is un-requested by next inspection, give it *one more chance*.
- Thereafter, if un-requested since last inspection, replace.

*Is philosophy that of a
marking algorithm?*

Theorem:

If

(Algorithm CLOCK, prior to end of a k-phase, evicts at least one page after first request for that page)

then

(Algorithm CLOCK is NOT a marking algorithm.)

Sufficient to Demonstrate:

Algorithm CLOCK, operating with a fast memory of k pages, on the i^{th} k -phase of σ :

- Services a **1st request** $\sigma_{i:[h+0](<k)}$ for a **page x** ,
- **Evicts page x** in servicing a 1st request $\sigma_{i:[h+m+0](<k+1)}$ for a different page y , and then
- Later encounters a **2nd request** $\sigma_{i:[h+m+r](<k+1)}$ for **page x** which must fault.

Primary Assumption in Example:

*Initial configuration
(pages-in-cache,
visitation status of each,
and current position of
clock) is reachable.*

CSE 5314 – "On-line Computation" Homework Set 01 File: HW01PPL

Example:

Initial configuration of fast memory as k -phase $i-1$ is about to end with the $k+1$ first request: clock = 6.

Red = bit is SET; Green = bit is CLR.

..	f	..	e	..	d	<i>k</i> -phase <i>i</i>				
						a	x	b	y	x
						1	2	3	4	5

σ	h	Counter Action	Flag Is	Page & Flag Action	
<i>Last σ_h of k-phase $i-1$</i>					
a	1	Tally	1 CLR	LOAD: Evict <i>g</i> SET	
x	2	-	1 -	- SET	
b	3	Tally	2 SET	- CLR	
		Tally	3 CLR	LOAD: Evict <i>h</i> SET	
y	4	Tally	4 SET	- CLR	
		Tally	5 SET	- CLR	
		Tally	6 SET	- CLR	
		Tally	1 SET	- CLR	
		Tally	2 CLR	LOAD: Evict <i>x</i> SET	
x	5	Faults on 2 nd request for same page in same k -phase.

Therefore:

*This variant of CLOCK (one more chance) is **NOT** a marking algorithm. Q.E.D.*

But, before closing ...

What about other variants?

How about a you-specify-the-number-of-chances CLOCK algorithm?

- *Instead of one bit, have n bits and afford from zero to 2^n more chances.*
- *Zero-more-chances fails like one-more-chance, only sooner.*
- *Will 2^n more chances also fail, only later?*
